5 (f) The Dependent Product and \exists

5 (g) Derivations vs. Agda Code

5 (h) Presuppositions

5 (i) The Full Logical Framework

5 (a) Judgements

- ▶ In the λ -calculus, it is easy to determine the correctly formed types. In dependent type theory the type structure is richer and more complicated.
- ▶ Proof steps are required to conclude that something is a type.

Judgements

- Therefore we have not only the judgement as in the λ -calculus

$$a : A$$

but as well a typing judgement A is a type, written (as we have already seen)

$$A : \text{Set}$$

- Before deriving $a : A$, we first have to show $A : \text{Set}$.
 - So any derivation of $a : A$ contains implicitly a derivation of $A : \text{Set}$.

Equality Judgements

- ▶ Agda will identify terms which have the same normal form.
E.g. $s := (\lambda x^A. x) r$ and r will be identified.
- ▶ If one needs at some place r , one can insert s instead of r and vice versa.
- ▶ In Agda this is done automatically, the user doesn't see such equalities.
 - ▶ There is not even a direct command available in Agda, which allows to check whether two terms are equal (this could probably be added easily).

[Jump over example.](#)

Example

```

postulate A : Set
postulate a : A
postulate P : A → Set
g      :   A → A
g a    =   a

```

```

a'      :   A
a'      =   g a
p       :   P a → P a'
p x     =   {! !}

```

exampleSimpleEquality2.agda

Since $a' = g\ a = a$, we can solve the goal by using `x`.

Equality Judgements

- ▶ When using the simply typed λ -calculus, we could separate the derivation of λ -terms, from reductions.
- ▶ When using dependent type theory as in Agda, reductions and derivations have to be integrated.
- ▶ Traditionally, instead of introducing reductions, one introduces in dependent type theory equalities between terms.
- ▶ Written as

$$r = s : A$$

for r and s are equal elements of set A .

Example

- ▶ The rule expressing that $\pi_0(\langle a, b \rangle) \rightarrow a$ reads in this style as follows:

$$\frac{a : A \quad b : B}{\pi_0(\langle a, b \rangle) = a : A} (\times\text{-Eq}_0)$$

- ▶ $=$ is not directed, so we have as well the rule

$$\frac{a = b : A}{b = a : A} (\text{Sym}_{\text{Elem}})$$

- ▶ We can therefore derive:

$$\frac{\frac{a : A \quad b : B}{\pi_0(\langle a, b \rangle) = a : A} (\times\text{-Eq}_0)}{a = \pi_0(\langle a, b \rangle) : A} (\text{Sym}_{\text{Elem}})$$

Equality of Types

- ▶ We will have as well equality between types, written as

$$A = B : \text{Set}$$

- ▶ This is something novel in dependent type theory.
 - ▶ In simple type theory, there is only one way of writing a type.

Examples (Equality of Types)

- ▶ Assume $f : A \rightarrow \text{Set}$.

If $a = a' : A$, then

$$f\ a = f\ a' : \text{Set} .$$

- ▶ We used this in the [example above](#):

- ▶ There we had

$$x : f\ a$$

and could by $f\ a = f\ a'$ conclude

$$x : f\ a'$$

[Jump over next examples.](#)

Examples (Equality of Types)

- More precisely this follows by the following derivation (the equality rule used here will be introduced in Subsect. (d)).

$$\frac{x : f \ a \quad \frac{f : A \rightarrow A \quad a = a' : A}{f \ a = f \ a' : \text{Set}}}{x : f \ a'}$$

Examples (Equality of Types)

- ▶ Above we have defined $\text{o2} = \text{o} \rightarrow \text{o}$.
As a judgement this reads:

$$\text{o2} = \text{o} \rightarrow \text{o} : \text{Set} .$$

Four Judgements

So we have the following **4 types of judgements**:

$A : \text{Set}$ “ A is a type”.

$A = B : \text{Set}$ “ A and B are equal types”.

$a : A$ “ a is of type A ”.

$a = b : A$ “ a and b are equal elements of type A ”.

In Agda, only $A : \text{Set}$ and $a : A$ are explicit.

Dependent Judgements

- ▶ As for the simply typed λ -calculus, in dependent type theory, judgements might depend on a **context**.
- ▶ So we obtain judgements of the form

$$x_1 : A_1, \dots, x_n : A_n \Rightarrow A : \text{Set}$$

$$x_1 : A_1, \dots, x_n : A_n \Rightarrow A = B : \text{Set}$$

$$x_1 : A_1, \dots, x_n : A_n \Rightarrow a : A$$

$$x_1 : A_1, \dots, x_n : A_n \Rightarrow a = b : A$$

Need for Context Judgements

$$x_1 : A_1, \dots, x_n : A_n \Rightarrow A : \text{Set}$$

...

- To derive such judgements requires that we know

$$\begin{array}{rcl} & & A_1 : \text{Set} \\ & x_1 : A_1 & \Rightarrow A_2 : \text{Set} \\ x_1 : A_1, x_2 : A_2 & \Rightarrow & A_3 : \text{Set} \\ & & \dots \end{array}$$

$$x_1 : A_1, x_2 : A_2, \dots, x_{n-1} : A_{n-1} \Rightarrow A_n : \text{Set}$$

- (Later, when we introduce higher types, this requirement has to be replaced by $A_1 : \text{Type}$, $x_1 : A_1 \Rightarrow A_2 : \text{Type}$ etc.)

[Jump over next slide](#)

Context Judgement

- ▶ Note that we didn't require derivations as above in the simply typed λ -calculus, since it was easy to verify whether something is a valid type.
- ▶ In case of dependent types $A : \text{Set}$ requires a derivation.
- ▶ It can be as complicated to derive $A : \text{Set}$ as it is to derive a judgement $b : B$:
One can compute from a statement $a : A$ (of which we don't know whether it is type correct) an expression B s.t.
$$a : A \text{ holds iff } B : \text{Set} \text{ holds.}$$

Context Judgement

- ▶ In order to organise this in a better way we introduce an additional judgement $\Gamma \Rightarrow \text{Context}$ for “ Γ is a valid context”.
- ▶ That $x_1 : A_1, \dots, x_n : A_n \Rightarrow \text{Context}$ holds means exactly what we had above, i.e.:

$$\begin{array}{rcl}
 & & A_1 : \text{Set} \\
 & x_1 : A_1 & \Rightarrow A_2 : \text{Set} \\
 x_1 : A_1, x_2 : A_2 & \Rightarrow & A_3 : \text{Set} \\
 & \dots & \\
 x_1 : A_1, x_2 : A_2, \dots, x_{n-1} : A_{n-1} & \Rightarrow & A_n : \text{Set}
 \end{array}$$

Five Dependent Judgements

- We have therefore 5 dependent judgements:

$$x_1 : A_1, \dots, x_n : A_n \Rightarrow A : \text{Set}$$

$$x_1 : A_1, \dots, x_n : A_n \Rightarrow A = B : \text{Set}$$

$$x_1 : A_1, \dots, x_n : A_n \Rightarrow a : A$$

$$x_1 : A_1, \dots, x_n : A_n \Rightarrow a = b : A$$

$$x_1 : A_1, \dots, x_n : A_n \Rightarrow \text{Context}$$

Example

- The assumption rule, which in case of the simply typed λ -calculus read

$$\Gamma, x : \sigma, \Delta \Rightarrow x : \sigma \quad (\text{if } x : \tau \text{ does not occur in } \Delta \text{ for any } \tau)$$

reads in dependent type theory as follows (assuming that $x : B$ does not occur in Δ for any B):

$$\frac{\Gamma, x : A, \Delta \Rightarrow \text{Context}}{\Gamma, x : A, \Delta \Rightarrow x : A} \text{ (Ass)}$$

- Similarly we have to deal with the rule introducing constants.

Notations for Judgements, Contexts

- ▶ θ (pronounced “theta”) will in the following denote an arbitrary non-dep. judgement, i.e. one of the following :
 - ▶ $A : \text{Set}$,
 - ▶ $A = B : \text{Set}$,
 - ▶ $a : A$,
 - ▶ $a = b : A$.
- ▶ Γ, Δ will usually denote contexts.
- ▶ We have the same notations as before, i.e.
 - ▶ Γ, Δ is the result of concatenating contexts Γ, Δ ,
 - ▶ $\Gamma, x : A$ is the result of extending the context Γ by $x : A$,
 - ▶ \emptyset is the empty context.
 - ▶ We write for $\emptyset \Rightarrow \theta$ usually simply θ .

Contexts in Agda

- ▶ In Agda, we have no explicit judgements depending on contexts.
 - ▶ Not needed, since we don't derive judgements using rules directly.
- However, if we have the open judgement

$$\begin{array}{lcl} f & : & B \rightarrow A \\ f\ x & = & \{! \ !\} \end{array}$$

- ▶ Then we can make use of $x : B$ for refining the goal.
- ▶ So we have to solve the goal in context $x : B$.
- ▶ This context can be shown using goal menu **Context (environment)**.
- ▶ See **[exampleShowContext.agda](#)**.

Contexts in Agda

- ▶ [Jump over the next example.](#)

Example: Derivation of double

(See [exampleDoubleString2.agda](#).)

- ▶ We derive $\text{double} := \lambda x^{\text{String}}.\text{concat } x \ x : ((x : \text{String}) \rightarrow \text{String})$ in Agda, assuming definitions of `String` and `concat`.
- ▶ We start with

$$\begin{aligned} \text{double} & : \text{String} \rightarrow \text{String} \\ \text{double } s & = \{! \ !\} \end{aligned}$$

- ▶ We can insert into the goal `concat`:

$$\begin{aligned} \text{double} & : \text{String} \rightarrow \text{String} \\ \text{double } s & = \{! \ \text{concat} \ !\} \end{aligned}$$

Example: Derivation of double

- ▶ When using goal-menu **refine**, we obtain:

$$\begin{array}{ll} \text{double} & : \quad \text{String} \rightarrow \text{String} \\ \text{double } s & = \quad \text{concat } \{! \ !\} \{! \ !\} \end{array}$$

- ▶ We can check now using goal-menu **Goal Type** (or **Goal Type (normalised)**) that the two new goals require both type `String`.
- ▶ We can check using goal-menu **Context (environment)** that the context of both goals contain `x : String`.

Example: Derivation of double

- ▶ We insert x into the first goal and refine:

$$\begin{array}{ll} \text{double} & : \text{String} \rightarrow \text{String} \\ \text{double } s & = \text{concat } x \{! \ !\} \end{array}$$

- ▶ Doing the same with the second goal gives:

$$\begin{array}{ll} \text{double} & : \text{String} \rightarrow \text{String} \\ \text{double } s & = \text{concat } x \ x \end{array}$$

- ▶ We are done.

double in Type Theory

A derivation of

$$\text{double} := \lambda x^{\text{String}}. \text{double } x \ x$$

in Type Theory, assuming global constants

$\text{String} : \text{Set}$,

$\text{concat} : \text{String} \rightarrow \text{String} \rightarrow \text{String}$,

is as follows:

We first derive $x : \text{String} \Rightarrow \text{Context}$:

$$\frac{\emptyset : \text{Context} \quad \text{String} : \text{Set}}{x : \text{String} \Rightarrow \text{Context}} (\text{Context}_1)$$

double in Type Theory

- ▶ We derive $x : \text{String} \Rightarrow x : \text{String}$ using the previous derivation:

$$\frac{x : \text{String} \Rightarrow \text{Context}}{x : \text{String} \Rightarrow x : \text{String}} \text{Ass}$$

- ▶ We derive

$$x : \text{String} \Rightarrow \text{concat} : \text{String} \rightarrow \text{String} \rightarrow \text{String}$$

using $x : \text{String} \Rightarrow \text{Context}$ as follows:

$$\frac{\text{concat} : \text{String} \rightarrow \text{String} \rightarrow \text{String} \quad x : \text{String} \Rightarrow \text{Context}}{x : \text{String} \Rightarrow \text{concat} : \text{String} \rightarrow \text{String} \rightarrow \text{String}} \text{(Weak)}$$

double in Type Theory

- ▶ We derive $x : \text{String} \Rightarrow \text{concat } x : \text{String} \rightarrow \text{String}$ using the previous derivations:

$$\frac{x:\text{String} \Rightarrow \text{concat}:\text{String} \rightarrow \text{String} \rightarrow \text{String} \quad x:\text{String} \Rightarrow x:\text{String}}{x:\text{String} \Rightarrow \text{concat } x:\text{String} \rightarrow \text{String}} \quad (\rightarrow\text{-El})$$

- ▶ The remaining derivation using the above derivations is as follows:

$$\frac{\frac{x:\text{String} \Rightarrow \text{concat } x:\text{String} \rightarrow \text{String} \quad x:\text{String} \Rightarrow x:\text{String}}{x:\text{String} \Rightarrow \text{concat } x \ x:\text{String}} \quad (\rightarrow\text{-El})}{\text{double} := \lambda x^{\text{String}}. \text{concat } x \ x:\text{String} \rightarrow \text{String}} \quad (\rightarrow\text{-I})$$

5 (a) Judgements

5 (b) Basic Form of Rules

5 (d) Structural Rules

5 (e) The Dependent Function Set and \forall

5 (f) The Dependent Product and \exists

5 (g) Derivations vs. Agda Code

5 (h) Presuppositions

5 (i) The Full Logical Framework

Four Kinds of Rules

- ▶ For each set or type construction we have usually 4 kinds of rules:
 - (1) **Formation Rules.**
 - (2) **Introduction Rules.**
 - (3) **Elimination Rules.**
 - (4) **Equality Rules.**
- ▶ Additionally there are **equality versions of the formation, introduction and elimination rules.**

(1) Formation Rules

- ▶ The formation rules introduce new sets or types.
- ▶ Each set and type construction has one such rule.
- ▶ The **conclusion** of such a rule will have the form:

$$C \ a_1 \ \cdots \ a_n : \text{Set} \ .$$

- ▶ where C is a set-constructor,
 - ▶ a_1, \dots, a_n are its arguments.
 - ▶ $n = 0$ is possible.
- ▶ Later, we will introduce higher levels $\text{Type}, \text{Kind}, \dots$. Then we have formation rules with conclusion $C \ a_1 \ \cdots \ a_n : \text{Type}$ (or $: \text{Kind}$, etc.) and C is called a Type-constructor, Kind-constructor, etc.

Logical Framework

- ▶ Preliminarily, we will be using type theory without the full logical framework.
- ▶ For instance, below we will introduce

$\text{List } A : \text{Set}$

for any $A : \text{Set}$, the set of lists of elements of A .

Logical Framework

- ▶ Until we have introduced the full logical framework, it doesn't make sense to talk about `List` itself, which would have type

$$\text{List} : \text{Set} \rightarrow \text{Set} .$$

The problem is that $\text{Set} \rightarrow \text{Set}$ doesn't make sense without the logical framework.

- ▶ The full logical framework is conceptually more difficult, that's why we delay its introduction.
- ▶ When it is introduced, we can introduce

$$\text{List} : \text{Set} \rightarrow \text{Set}$$

similarly for all other set formation constructors.

Logical Framework

- ▶ Agda has the logical framework built in, so in Agda `List` will be a function $\text{Set} \rightarrow \text{Set}$, in Agda notation:

$$\begin{aligned}\text{List} & : \text{Set} \rightarrow \text{Set} \\ \text{List } A & = \{! \ !\}\end{aligned}$$

Example 1: The Set of Lists

$$\frac{A : \text{Set}}{\mathbf{List} \ A : \text{Set}} \text{ (List-F)}$$

- ▶ The **set-constructor** is **List**.
- ▶ List A is the set of lists of elements of A .
- ▶ The F in the label (List-F) stands for **F**ormation rule.

Ex. 2: The Set of Natural Numbers

- ▶ Formation rule for the set of natural numbers:

$$\mathbb{N} : \text{Set} \quad (\mathbb{N}\text{-F})$$

- ▶ The **set-constructor** is **N**.
 - ▶ Note that the formation rule for \mathbb{N} has 0 premises (therefore the fraction bar is omitted).

[Jump over next example and Agda](#)

Ex. 3: The Non-Dependent Product

- Formation rule for the non-dependent product:

$$\frac{A : \text{Set} \quad B : \text{Set}}{A \times B : \text{Set}} (\times\text{-F})$$

- $A \times B$ stands for $(\times) A B$.
- The **set-constructor** is (\times) .

Formation Rules in Agda

- ▶ The formation of a set is usually done by introducing a constant of a certain set.
- ▶ **Example 1:**

$$\begin{aligned}\text{List} &: \text{Set} \rightarrow \text{Set} \\ \text{List } A &= \{! \ !\}\end{aligned}$$

Example 2: (\times)

- Agda syntax for introducing the **non-dependent product**:

$$\begin{aligned} _ \times _ &: \text{Set} \rightarrow \text{Set} \rightarrow \text{Set} \\ A \times B &= \{! \ !\} \end{aligned}$$

(2) Introduction Rules

- ▶ The introduction rule introduces elements of a set.
- ▶ The **conclusion** of such a rule will have the form

$$C \ a_1 \ \cdots \ a_n : A$$

where

- ▶ A is a set introduced by the corresponding formation rule,
- ▶ C is a **constructor** or **term-constructor**,
- ▶ a_1, \dots, a_n are terms (can be elements of other sets, or sets or types themselves).

Introduction Rule, Example 1a

- ▶ The set `NatList` of lists of natural numbers with formation rule

$$\text{NatList} : \text{Set} \quad (\text{NatList-F})$$

has two introduction rules:

$$[] : \text{NatList} \quad (\text{NatList-I}[])$$

$$\frac{n : \mathbb{N} \quad l : \text{NatList}}{n :: l : \text{NatList}} \quad (\text{NatList-I}_{::})$$

- ▶ The I in the labels $(\text{NatList-I}[])$, $(\text{NatList-I}_{::})$ stands for Introduction rule.

[Jump to Example 2](#)

Introduction Rule, Example 1b

- ▶ We generalise the previous example to lists of arbitrary set.
- ▶ **Lists** of elements in A have two introduction rules:

$$\frac{A : \text{Set}}{[]_A : \text{List } A} (\text{List-I}[])$$

$$\frac{A : \text{Set} \quad a : A \quad l : \text{List } A}{a ::_A l : \text{List } A} (\text{List-I}_{::})$$

- ▶ Note that we need the **premise** $A : \text{Set}$ in order to guarantee that we can form the set $\text{List } A$.

Conflicting Constructors

- ▶ We shouldn't use the same constructors for different sets. So if we want to use both `NatList` and `List A`, we have to choose a notation like `natnil` instead of `[] : NatList`, similarly for `_ :: _`.
- ▶ We will usually ignore this distinction, if it doesn't cause confusion.

Example 2: Natural Numbers.

- ▶ The **natural numbers** \mathbb{N} can be considered as being formed from two operations:
 - ▶ 0,
 - ▶ S where S n stands for $n + 1$.
- ▶ Using these two operations we can form 0, S 0 = 1, S 1 = 2, ... and therefore all natural numbers.
 - ▶ So the **constructors** of \mathbb{N} are 0 and S.
- ▶ The **introduction rules** of \mathbb{N} are:

$$0 : \mathbb{N} \quad (\mathbb{N}\text{-I}_0)$$

$$\frac{n : \mathbb{N}}{S\ n : \mathbb{N}} \quad (\mathbb{N}\text{-I}_S)$$

Canonical Elements

- ▶ Canonical elements of a set are those introduced by an introduction rule.
- ▶ Canonical elements therefore always start with a **constructor**.
- ▶ **Examples:**
 - ▶ $0, S(2 + 3)$ in case of \mathbb{N} .
 - ▶ Here 2 stands for $S(S\ 0)$ and 3 for $S(S(S\ 0))$.
 - ▶ $[], (1 + 1) :: (\text{concat } (0 :: []) [])$ in case of NatList .

Non-Canonical Elements

- ▶ Terms can usually be reduced further

- ▶ Example:

$$2 + 3 = 2 + S\ 2 \longrightarrow S\ (2 + 2) .$$

- ▶ The underlying reduction system is essentially a term rewriting system combined with the λ -calculus.
 - ▶ Therefore we can apply reductions to subterms.
- ▶ A term is a non-canonical element of a set, if it **reduces to a canonical element** of that set.
 - ▶ Each element of a set (depending on the empty context) in dependent type theory will either be a canonical or a non-canonical element of that set.
 - ▶ Consequence of the normalisation theorem.

Non-Canonical Elements

- ▶ E.g. $2 + 3$ is a non-canonical element of \mathbb{N} , since $S(2 + 2)$ is a canonical element of \mathbb{N} .
- ▶ However, we have

$$x : \mathbb{N} \Rightarrow x : \mathbb{N}$$

and x doesn't reduce to a canonical element of \mathbb{N} .

- ▶ However, if we substitute for x any closed element of \mathbb{N} , we get a canonical or non-canonical element of \mathbb{N} .

(3) Elimination Rules

- **Elimination rules** allow to take an element of a set and **compute from it an element of another set**.
- Example 1: The introduction rule for the non-dependent product is

$$\frac{a : A \quad b : B}{\langle a, b \rangle : A \times B} (\times\text{-I})$$

The elimination rules (indicated by label El) are the first and second projections:

$$\frac{c : A \times B}{\pi_0(c) : A} (\times\text{-El}_0) \quad \frac{c : A \times B}{\pi_1(c) : B} (\times\text{-El}_1)$$

- The equality rules will express $\pi_0(\langle a, b \rangle) = a$, $\pi_1(\langle a, b \rangle) = b$.

Example 2: Addition in \mathbb{N}

$$\frac{n : \mathbb{N} \quad m : \mathbb{N}}{n + m : \mathbb{N}} \text{ (N-El}_+\text{)}$$

- ▶ Equality rules will express
 - ▶ $n + 0 = n$.
 - ▶ $n + S\ m = S\ (n + m)$.
- ▶ The equality rules show that n is only a parameter, we are eliminating the second argument m .
- ▶ Proceeding like this would require **one elimination rule for each function** from \mathbb{N} we want to define.
- ▶ Instead we will later introduce one **generic elimination rule**, which will allow to **introduce all functions** we expect to be definable, including **all primitive-recursive** ones.

Elimination in Agda

- ▶ Elimination for builtin sets has special notation.
- ▶ For user defined sets, i.e. those introduced using `data`, elimination is realized by **pattern matching**.
- ▶ Example: Definition of addition in \mathbb{N} :

$$\begin{aligned}
 & _ + _ && : \quad \mathbb{N} \rightarrow \mathbb{N} \rightarrow \mathbb{N} \\
 n + Z &= n \\
 n + S\ m &= S\ (n + m)
 \end{aligned}$$

(4) Equality Rules

- ▶ Equality rules will express what happens when we first introduce an element and then eliminate it.
- ▶ For instance if we first introduce $0 : \mathbb{N}$ and then eliminate it by using $(\mathbb{N}\text{-El}_+)$ we obtain $n + 0$.
 - ▶ Now $n + 0$ should reduce to n .
 - ▶ Since in dependent type theory we don't derive reductions but equalities, which is the transitive, symmetric and reflexive closure of \longrightarrow , we obtain $n + 0 = n : \mathbb{N}$ instead.
 - ▶ The equality rule (indicated by label Eq) expresses this:

$$\frac{n : \mathbb{N}}{n + 0 = n : \mathbb{N}} (\mathbb{N}\text{-Eq}_{+,0})$$

Equality Rules

- ▶ Similarly, if we introduce first $S\ m : \mathbb{N}$ and then eliminate it using $(\mathbb{N}\text{-El}_+)$ we obtain $n + S\ m$ which should reduce to $S\ (n + m)$.
 - ▶ The corresponding equality rule is therefore:

$$\frac{n : \mathbb{N} \quad m : \mathbb{N}}{n + S\ m = S\ (n + m) : \mathbb{N}} (\mathbb{N}\text{-Eq}_{+,S})$$

[Jump over next examples](#)

Example (Equality Rule)

- ▶ A third example is if we first introduce an element $\langle a, b \rangle : A \times B$ and then eliminate it using $(\times\text{-El}_0)$ we obtain $\pi_0(\langle a, b \rangle)$ which reduces to a .
- ▶ The corresponding equality rule is therefore:

$$\frac{a : A \quad b : B}{\pi_0(\langle a, b \rangle) = a : A} (\times\text{-Eq}_0)$$

Example (Equality Rule)

- ▶ The first equality rule for $A \times B$ is as follows:

$$\frac{a : A \quad b : B}{\pi_0(\langle a, b \rangle) = a : A} (\times\text{-Eq}_0)$$

- ▶ In the first judgement we can derive $\pi_0(\langle a, b \rangle) : A$ as follows:

$$\frac{\frac{a : A \quad b : B}{\langle a, b \rangle : A \times B} (\times\text{-I})}{\pi_0(\langle a, b \rangle) : A} (\times\text{-El}_0)$$

- ▶ So it is derived by first introducing $\langle a, b \rangle$ and then eliminating it immediately.
- ▶ The equality rule explains how to reduce that element (namely to $a : A$).

Example (Equality Rule, Cont)

- The second equality rule for \times is similar:

$$\frac{a : A \quad b : B}{\pi_1(\langle a, b \rangle) = b : B} (\times\text{-Eq}_1)$$

Example 2 (Equality Rule)

- ▶ The first equality rule for $+$ is as follows:

$$\frac{n : \mathbb{N}}{n + 0 = n : \mathbb{N}} (\mathbb{N}\text{-Eq}_{+,0})$$

- ▶ $n + 0 : \mathbb{N}$ can be derived by first introducing

$$0 : \mathbb{N}$$

(this is an introduction rule with no premises, i.e. an axiom)
and then by eliminating it using $+$, using the following derivation:

$$\frac{n : \mathbb{N} \quad 0 : \mathbb{N}}{n + 0 : \mathbb{N}} (\mathbb{N}\text{-El}_{+})$$

- ▶ The equality rule explain how to reduce $n + 0$.

Example 3 (Equality Rule)

- ▶ The second equality rule for $+$ is as follows:

$$\frac{n : \mathbb{N} \quad m : \mathbb{N}}{n + S \ m = S \ (n + m) : \mathbb{N}} \text{ (N-Eq}_{+,S}\text{)}$$

- ▶ $n + S \ m : \mathbb{N}$ can be derived by first introducing $S \ m : \mathbb{N}$ and then by eliminating it using $+$:

$$\frac{n : \mathbb{N} \quad \frac{m : \mathbb{N}}{S \ m : \mathbb{N}} \text{ (N-Is)}}{n + S \ m : \mathbb{N}} \text{ (N-El}_+\text{)}$$

Equality Rules in Agda

- ▶ Equality Rules in Agda are **implicit**.
- ▶ The notation for elimination however indicates already how the reductions take place.

$$\begin{array}{lcl}
 _ + _ & : & \mathbb{N} \rightarrow \mathbb{N} \rightarrow \mathbb{N} \\
 n + Z & = & n \\
 n + S\ m & = & S\ (n + m)
 \end{array}$$

- ▶ Functions corresponding to elimination are defined by telling **how elimination operates**.
[Jump over Reduction Strategy](#)

Reduction Strategy

- ▶ The canonical element for an element, which is the result of an elimination, can always be computed as follows:
 - ▶ Reduce the element to be eliminated to **canonical form**.
 - ▶ Then make one reduction step **(Red)**.
 - ▶ The result will be a **canonical or non-canonical element** of the target set.
Reduce it to canonical form.
- ▶ For instance in case of $A \times B$, (Red) are the reductions
 - ▶ $\pi_0(\langle a, b \rangle) \longrightarrow a.$
 - ▶ $\pi_1(\langle a, b \rangle) \longrightarrow b.$

Reduction Strategy

- ▶ In case of $(+)$, (Red) are the reductions
 - ▶ $n + 0 \longrightarrow n$.
 - ▶ $n + S\ m \longrightarrow S\ (n + m)$.
 - ▶ Note that the second argument is the argument which we are “eliminating”.

Example of the Reduction Strategy

- ▶ Consider for instance the term $(1 + 1) + (1 + 0)$, where $1 = S\ 0$.
- ▶ It is constructed by using the elimination constant $(+)$.
- ▶ The argument we are eliminating using $(+)$ is the second one $(1 + 0)$.
- ▶ So we first reduce this argument to canonical form:

$$1 + 0 \longrightarrow 1$$

and obtain

$$(1 + 1) + (1 + 0) \longrightarrow (1 + 1) + 1 \equiv (1 + 1) + S\ 0$$

Example of the Reduction Strategy

$$(1 + 1) + (1 + 0) \longrightarrow (1 + 1) + 1 \equiv (1 + 1) + S\ 0$$

- ▶ Now the argument we are eliminating in is in canonical form, and we can use the reduction rule $x + S\ y \longrightarrow S\ (x + y)$ in order to reduce this term:

$$(1 + 1) + S\ 0 \longrightarrow S\ ((1 + 1) + 0)$$

- ▶ The result is in this case already in canonical form.
- ▶ If it were not, we would continue with our reduction.
- ▶ However, even if our example is in canonical form, it can be further reduced:

$$S((1 + 1) + 0) \longrightarrow S\ (1 + 1) \equiv S\ (1 + S\ 0) \longrightarrow S\ (S\ 1) = 3$$

Equality Versions of the Rules

- ▶ We have equality versions of the formation, introduction, and elimination rules.
- ▶ These express: if we **replace the terms in the premises by equal ones, we obtain equal results**.
- ▶ Example: Equality version of the formation rule for List:

$$\frac{A = B : \text{Set}}{\text{List } A = \text{List } B : \text{Set}} \quad (\text{List-F}^=)$$

- ▶ Example: Equality version of the formation rule for \mathbb{N} (degenerated):

$$\mathbb{N} = \mathbb{N} : \text{Set} \quad (\mathbb{N}\text{-F}^=)$$

Equality Versions of Rules

- Example: Equality version of the introduction rules for List:

$$\frac{A = A' : \text{Set}}{[]_A = []_{A'} : \text{List } A} \text{ (List-I[]=)}$$

$$\frac{A = A' : \text{Set} \quad a = a' : A \quad l = l' : \text{List } A}{a ::_A l = a' ::_{A'} l' : \text{List } A} \text{ (List-I_{::}=)}$$

- Example: Equality version of the elimination rule for (+), \mathbb{N} :

$$\frac{n = n' : \mathbb{N} \quad m = m' : \mathbb{N}}{n + m = n' + m' : \mathbb{N}} \text{ (N-El_{+}^=)}$$

Equality Versions of Rules

- ▶ The equality versions of the rules in questions can be formed in a **straight-forward way**, once one knows the non-equality version.
 - ▶ We will often not mention them.
- ▶ In **Agda** they are **implicit** (part of the reduction machinery).

[Jump over Weakening Rule](#)

Common Contexts

- ▶ The convention is that all rules can as well be weakened by a common context.
- ▶ This means that when introducing a rule

$$\frac{\Gamma_1 \Rightarrow \theta_1 \quad \cdots \quad \Gamma_n \Rightarrow \theta_n}{\Gamma \Rightarrow \theta}$$

we implicitly introduce as well the following rules

$$\frac{\Delta, \Gamma_1 \Rightarrow \theta_1 \quad \cdots \quad \Delta, \Gamma_n \Rightarrow \theta_n}{\Delta, \Gamma \Rightarrow \theta}$$

- ▶ This convention will not apply to the context rules (Context_0) and (Context_1) (see later).

Example

- For instance, the formation rule of \times :

$$\frac{A : \text{Set} \quad B : \text{Set}}{A \times B : \text{Set}} (\times\text{-F})$$

can be weakened as follows:

$$\frac{\Gamma \Rightarrow A : \text{Set} \quad \Gamma \Rightarrow B : \text{Set}}{\Gamma \Rightarrow A \times B : \text{Set}} (\times\text{-F})$$

Example (Cont.)

- Consider the sample derivation (assuming $A : \text{Set}$):

$$\frac{\frac{x : A, y : A \Rightarrow y : A}{x : A \Rightarrow \lambda y^A. y : A \rightarrow A} (\rightarrow -I)}{\lambda x^A. \lambda y^A. y : A \rightarrow A \rightarrow A} (\rightarrow -I)$$

- The first rule used is the rule for λ -introduction, weakened by the context $x : A$.
- The second rule used is the rule for λ -introduction without any weakening.

Weakening of Axioms

- If we have an axiom

$$\theta$$

for any judgement θ

- e.g. $\theta \equiv N : \text{Set}$ or $\theta \equiv 0 : \mathbb{N}$

and we want to weaken it by context Γ , we need to make sure that $\Gamma \Rightarrow \text{Context}$ holds.

- So we need in the weakened form one additional premise:

$$\frac{\Gamma \Rightarrow \text{Context}}{\Gamma \Rightarrow \theta}$$

Example

- The formation rule for \mathbb{N}

$$\mathbb{N} : \text{Set} \quad (\text{N-F})$$

will be weakened as follows:

$$\frac{\Gamma \Rightarrow \text{Context}}{\Gamma \Rightarrow \mathbb{N} : \text{Set}} (\text{N-F})$$

5 (a) Judgements

5 (b) Basic Form of Rules

5 (c) The Nondependent Function Type and Product

5 (d) Structural Rules

5 (e) The Dependent Function Set and \forall

5 (f) The Dependent Product and \exists

5 (g) Derivations vs. Agda Code

5 (h) Presuppositions

5 (i) The Full Logical Framework

5 (c) The Nondependent Function Type and Product

We introduce in the following non-dependent versions of the product and the function set.

The Non-Dependent Product

Formation Rule
$$\frac{A : \text{Set} \quad B : \text{Set}}{A \times B : \text{Set}} (\times\text{-F})$$

Introduction Rule
$$\frac{a : A \quad b : B}{\langle a, b \rangle : A \times B} (\times\text{-I})$$

Elimination Rules
$$\frac{c : A \times B}{\pi_0(c) : A} (\times\text{-El}_0) \quad \frac{c : A \times B}{\pi_1(c) : B} (\times\text{-El}_1)$$

Equality Rules
$$\frac{a : A \quad b : B}{\pi_0(\langle a, b \rangle) = a : A} (\times\text{-Eq}_0)$$

$$\frac{a : A \quad b : B}{\pi_1(\langle a, b \rangle) = b : B} (\times\text{-Eq}_1)$$

The η -Rule

The η -rule does not fit into the above schema:

$$\frac{c : A \times B}{c = \langle \pi_0(c), \pi_1(c) \rangle : A \times B} (\times\text{-}\eta)$$

Equality Versions of the \times -Rules

Equality Version of the Formation Rule

$$\frac{A = A' : \text{Set} \quad B = B' : \text{Set}}{A \times B = A' \times B' : \text{Set}} (\times\text{-F}^=)$$

Equality Version of the Introduction Rule

$$\frac{a = a' : A \quad b = b' : B}{\langle a, b \rangle = \langle a', b' \rangle : A \times B} (\times\text{-I}^=)$$

Equality Versions of the Elimination Rules

$$\frac{c = c' : A \times B}{\pi_0(c) = \pi_0(c') : A} (\times\text{-El}_0^=) \quad \frac{c = c' : A \times B}{\pi_1(c) = \pi_1(c') : B} (\times\text{-El}_1^=)$$

The Non-Dependent Function Type

Formation Rule
$$\frac{A : \text{Set} \quad B : \text{Set}}{A \rightarrow B : \text{Set}} (\rightarrow\text{-F})$$

Introduction Rule
$$\frac{x : A \Rightarrow b : B}{(\lambda x : A. b) : A \rightarrow B} (\rightarrow\text{-I})$$

Elimination Rule
$$\frac{f : A \rightarrow B \quad a : A}{f \ a : B} (\rightarrow\text{-El})$$

Equality Rule
$$\frac{x : A \Rightarrow b : B \quad a : A}{(\lambda x : A. b) \ a = b[x := a] : B} (\rightarrow\text{-Eq})$$

As for the typed λ -calculus, $\lambda x^A. b$ is an abbreviation for $\lambda(x : A). b$.

β -Reduction

- ▶ $b[x := a]$ was as for the simply typed λ -calculus the result of substituting in b every occurrence of variable x by the term a (after renaming of bound variables as usual).
- ▶ The equality rule is a symmetric version of β -reduction

$$(\lambda x^A. b) a \longrightarrow b[x := a]$$

α -Equivalence

- ▶ As for the simply typed λ -calculus, terms which differ in the choice of bound variables (i.e. which are α -equivalent) are identified:
 - ▶ E.g. $\lambda x^A.x$ and $\lambda y^A.y$ are identified.
 - ▶ E.g. $\lambda x^{\mathbb{N}}.x + x$ and $\lambda y^{\mathbb{N}}.y + y$ are identified.
 - ▶ A similar rule applies to bound variables **in types** (see later).

The η -Rule

Again the η -rule does not fit into the above schema:

$$\frac{f : A \rightarrow B}{f = \lambda x^A. f \ x : A \rightarrow B} (\rightarrow -\eta)$$

Equality Versions of the \rightarrow -Rules

Equality Version of the Formation Rule

$$\frac{A = A' : \text{Set} \quad B = B' : \text{Set}}{A \rightarrow B = A' \rightarrow B' : \text{Set}} (\rightarrow\text{-F}^=)$$

Equality Version of the Introduction Rule

$$\frac{x : A \Rightarrow b = b' : B}{\lambda x^A. b = \lambda x^A. b' : A \rightarrow B} (\rightarrow\text{-I}^=)$$

Equality Version of the Elimination Rule

$$\frac{f = f' : A \rightarrow B \quad a = a' : A}{f\ a = f'\ a' : B} (\rightarrow\text{-E}^=)$$

[Jump over subsection on structural rules](#)

5 (a) Judgements

5 (b) Basic Form of Rules

5 (c) The Nondependent Function Type and Product

5 (d) Structural Rules

5 (e) The Dependent Function Set and \forall

5 (f) The Dependent Product and \exists

5 (g) Derivations vs. Agda Code

5 (h) Presuppositions

5 (i) The Full Logical Framework

Context Rules

The empty context

$$\emptyset \Rightarrow \text{Context} \quad (\text{Context}_0)$$

Extending a context

$$\frac{\Gamma \Rightarrow A : \text{Set}}{\Gamma, x : A \Rightarrow \text{Context}} (\text{Context}_1)$$

- The convention that rules can be weakened by a common context does not apply to the rules (Context_0) and (Context_1) .

Example Derivation (Context Rules)

- ▶ We assume the following formation rule for the set of natural numbers:

$$\mathbb{N} : \text{Set} \quad (\text{N-F})$$

- ▶ With this rule, following the convention on the previous slide we have as well introduced the rules

$$\frac{\Gamma \Rightarrow \text{Context}}{\Gamma \Rightarrow \mathbb{N} : \text{Set}} \quad (\text{N-F})$$

Example Derivation (Context Rules)

- ▶ The following derives $x : \mathbb{N}, y : \mathbb{N}, z : \mathbb{N} \Rightarrow \text{Context}$
(Note that $\mathbb{N} : \text{Set}$ is the same as $\emptyset \Rightarrow \mathbb{N} : \text{Set}$):

$$\begin{array}{c}
 \frac{\mathbb{N} : \text{Set}}{x : \mathbb{N} \Rightarrow \text{Context}} \text{ (Context}_1\text{)} \\
 \frac{x : \mathbb{N} \Rightarrow \text{Context}}{x : \mathbb{N} \Rightarrow \mathbb{N} : \text{Set}} \text{ (N-F)} \\
 \frac{x : \mathbb{N} \Rightarrow \mathbb{N} : \text{Set}}{x : \mathbb{N}, y : \mathbb{N} \Rightarrow \text{Context}} \text{ (Context}_1\text{)} \\
 \frac{x : \mathbb{N}, y : \mathbb{N} \Rightarrow \text{Context}}{x : \mathbb{N}, y : \mathbb{N} \Rightarrow \mathbb{N} : \text{Set}} \text{ (N-F)} \\
 \frac{x : \mathbb{N}, y : \mathbb{N} \Rightarrow \mathbb{N} : \text{Set}}{x : \mathbb{N}, y : \mathbb{N}, z : \mathbb{N} \Rightarrow \text{Context}} \text{ (Context}_1\text{)}
 \end{array}$$

Assumption Rule

$$\frac{\Gamma, x : A, \Delta \Rightarrow \text{Context}}{\Gamma, x : A, \Delta \Rightarrow x : A} (\text{Ass})$$

► **Side condition Δ must not bind x again:**

Δ must not be of the form $\Delta', x : B, \Delta''$ for some Δ', B, Δ'' .

- Otherwise the assumption $x : B$ would override the assumption $x : A$.
- If $x : B$ occurs in Δ , we can only conclude

$$\Gamma, x : A, \Delta \Rightarrow x : B'$$

only for the last occurrence of $x : B'$ in Δ .

Example Deriv. (Assumpt. Rule)

- We extend the derivation of

$$x : \mathbb{N}, y : \mathbb{N}, z : \mathbb{N} \Rightarrow \text{Context}$$

above to a derivation of $x : \mathbb{N}, y : \mathbb{N}, z : \mathbb{N} \Rightarrow y : \mathbb{N}$:

$$\frac{x : \mathbb{N}, y : \mathbb{N}, z : \mathbb{N} \Rightarrow \text{Context}}{x : \mathbb{N}, y : \mathbb{N}, z : \mathbb{N} \Rightarrow y : \mathbb{N}} (\text{Ass})$$

- Similarly we can derive $x : \mathbb{N}, y : \mathbb{N}, z : \mathbb{N} \Rightarrow z : \mathbb{N}$:

$$\frac{x : \mathbb{N}, y : \mathbb{N}, z : \mathbb{N} \Rightarrow \text{Context}}{x : \mathbb{N}, y : \mathbb{N}, z : \mathbb{N} \Rightarrow z : \mathbb{N}} (\text{Ass})$$

Example Deriv. (Assumpt. Rule)

- The full derivation of first judgement on the previous slide is as follows:

$$\begin{array}{c}
 \frac{\mathbb{N} : \text{Set}}{x : \mathbb{N} \Rightarrow \text{Context}} \text{ (Context}_1\text{)} \\
 \frac{x : \mathbb{N} \Rightarrow \text{Context}}{x : \mathbb{N} \Rightarrow \mathbb{N} : \text{Set}} \text{ (N-F)} \\
 \frac{x : \mathbb{N}, y : \mathbb{N} \Rightarrow \text{Context}}{x : \mathbb{N}, y : \mathbb{N} \Rightarrow \mathbb{N} : \text{Set}} \text{ (Context}_1\text{)} \\
 \frac{x : \mathbb{N}, y : \mathbb{N} \Rightarrow \mathbb{N} : \text{Set}}{x : \mathbb{N}, y : \mathbb{N}, z : \mathbb{N} \Rightarrow \text{Context}} \text{ (N-F)} \\
 \frac{x : \mathbb{N}, y : \mathbb{N}, z : \mathbb{N} \Rightarrow \text{Context}}{x : \mathbb{N}, y : \mathbb{N}, z : \mathbb{N} \Rightarrow y : \mathbb{N}} \text{ (Context}_1\text{)} \\
 \text{ (Ass)}
 \end{array}$$

Assumption Rule in Agda

- ▶ When we define a function:

$$\begin{aligned} f & : A \rightarrow B \\ f\ a & = \{! \ !\} \end{aligned}$$

we can make use of $a : A$ when solving the goal $\{! \ !\}$.

- ▶ This is an application of the assumption rule:
When solving $\{! \ !\}$ we essentially define
under the assumption $a : A$ an element $\{! \ !\} : B$.

Assumption Rule in Agda (Cont.)

- The above corresponds to a derivation

$$\frac{a : A \Rightarrow \{! \ !\} : B}{\lambda(a : A).\{! \ !\} : A \rightarrow B} (\rightarrow\text{-I})$$

- If B is equal to A we can use the assumption rule directly

$$\frac{a : A \Rightarrow a : A}{\lambda(a : A).a : A \rightarrow A} (\rightarrow\text{-I})$$

in order to solve this goal.

Assumption Rule in Agda (Cont.)

- More generally we might in the derivation of $a : A \Rightarrow \{! \ !\} : B$ make anywhere use of $a : A$, as long as this is in the context.

$$\frac{\displaystyle \frac{\dots}{a : A \Rightarrow a : A} \text{ (Ass)}}{\displaystyle \frac{a : A \Rightarrow s : B}{\lambda(a : A).s : A \rightarrow B} \text{ } (\rightarrow\text{-I})}$$

Assumption Rule in Agda (Cont.)

- ▶ Similarly, when solving the goal

$$f : A \rightarrow B$$

$$= \lambda(a : A) \rightarrow \{! \ !\}$$

in $\{! \ !\}$ we can make use of $a : A$.

- ▶ In fact when solving the above, we implicitly use the rule

$$\frac{a : A \Rightarrow \{! \ !\} : B}{\lambda(a : A).\{! \ !\} : A \rightarrow B} (\rightarrow -I)$$

So we have to solve $a : A \Rightarrow \{! \ !\} : B$ in order to derive

$$\lambda(a : A).\{! \ !\} : A \rightarrow B$$

Weakening Rule

$$\frac{\Gamma, \Gamma' \Rightarrow \theta \quad \Gamma, \Delta, \Gamma' \Rightarrow \text{Context}}{\Gamma, \Delta, \Gamma' \Rightarrow \theta} \text{ (Weak)}$$

- ▶ θ stands for an **arbitrary non-dependent judgement**.
- ▶ This rule allows to **add an additional context piece** (Δ) to the **context of a judgement**.
 - ▶ The judgement $\Gamma, \Gamma' \Rightarrow \theta$ is weakened by Δ .

Weakening Rule (Cont.)

- ▶ Remark: One can in fact show that the weakening rule can be **weakly derived**.
 - ▶ Weakly derived means: whenever the assumptions of the rule can be derived in the complete set of rules we provide, then as well the conclusion.
 - ▶ However, this can't be derived from the premise the conclusion directly.
- ▶ An exception is when we **additionally assume some judgements** for instance $A : \text{Set}$ (corresponding to “postulate” in Agda).
 - ▶ Then $\Gamma \Rightarrow A : \text{Set}$ doesn't follow without the weakening rule.

Example Deriv. (Weak. Rule)

- We derive $a : A, b : B \Rightarrow a : A$, under the global assumptions $A : \text{Set}$, $B : \text{Set}$:

$$\frac{\frac{\frac{A:\text{Set}}{a:A \Rightarrow \text{Context}} \text{ (Context}_1\text{)}}{a:A \Rightarrow a:A} \text{ (Ass)} \quad \frac{\frac{\frac{B:\text{Set}}{a:A \Rightarrow B:\text{Set}} \text{ (Context}_1\text{)}}{a:A, b:B \Rightarrow \text{Context}} \text{ (Weak)}}{a:A, b:B \Rightarrow a:A} \text{ (Weak)}$$

Example Deriv.2 (Weak. Rule)

- We derive $x : A \rightarrow (B \times C), y : A \Rightarrow x : A \rightarrow (B \times C)$, under the global assumptions $A : \text{Set}, B : \text{Set}, C : \text{Set}$:

$$\begin{array}{c}
 \frac{A : \text{Set} \quad \frac{B : \text{Set} \quad C : \text{Set}}{B \times C : \text{Set}} (\times\text{-F})}{A \rightarrow (B \times C) : \text{Set}} (\rightarrow\text{-F}) \\
 \frac{A : \text{Set} \quad x : A \rightarrow (B \times C) \Rightarrow \text{Context}}{x : A \rightarrow (B \times C) \Rightarrow \text{Context}} (\text{Context}_1) \\
 \frac{x : A \rightarrow (B \times C) \Rightarrow \text{Context}}{x : A \rightarrow (B \times C) \Rightarrow A : \text{Set}} (\text{Weak}) \\
 \frac{x : A \rightarrow (B \times C), y : A \Rightarrow \text{Context}}{x : A \rightarrow (B \times C), y : A \Rightarrow x : A \rightarrow (B \times C)} (\text{Context}_1) \\
 \frac{x : A \rightarrow (B \times C), y : A \Rightarrow x : A \rightarrow (B \times C)}{x : A \rightarrow (B \times C), y : A \Rightarrow x : A \rightarrow (B \times C)} (\text{Ass})
 \end{array}$$

General Equality Rules

Reflexivity

$$\frac{A : \text{Set}}{A = A : \text{Set}} (\text{Refl}_{\text{Set}})$$

$$\frac{a : A}{a = a : A} (\text{Refl}_{\text{Elem}})$$

(Reflexivity can be weakly derived, except for global assumptions).

Symmetry

$$\frac{A = B : \text{Set}}{B = A : \text{Set}} (\text{Sym}_{\text{Set}})$$

$$\frac{a = b : A}{b = a : A} (\text{Sym}_{\text{Elem}})$$

General Equality Rules (Cont.)

Transitivity

$$\frac{A = B : \text{Set} \quad B = C : \text{Set}}{A = C : \text{Set}} (\text{Trans}_{\text{Set}})$$

$$\frac{a = b : A \quad b = c : A}{a = c : A} (\text{Trans}_{\text{Elem}})$$

Transfer

$$\frac{a : A \quad A = B : \text{Set}}{a : B} (\text{Transfer}_0)$$

$$\frac{a = b : A \quad A = B : \text{Set}}{a = b : B} (\text{Transfer}_1)$$

Example Deriv. (Gen. Equal. Rules)

$$\begin{array}{c}
 \frac{\frac{\frac{\mathbb{N}:\text{Set}}{y:\mathbb{N} \Rightarrow \text{Context}} \text{ (Context}_1\text{)}}{y:\mathbb{N} \Rightarrow y:\mathbb{N}} \text{ (Ass)}}{y:\mathbb{N} \Rightarrow y+0=y:\mathbb{N}} \text{ (N-Eq}_{+,0}\text{)} \\
 \\
 \frac{\frac{\frac{\frac{\mathbb{N}:\text{Set}}{y:\mathbb{N} \Rightarrow \text{Context}} \text{ (Context}_1\text{)}}{y:\mathbb{N} \Rightarrow \mathbb{N}:\text{Set}} \text{ (N-F)}}{\frac{\frac{y:\mathbb{N}, x:\mathbb{N} \Rightarrow \text{Context}}{y:\mathbb{N}, x:\mathbb{N} \Rightarrow x:\mathbb{N}} \text{ (Ass)}}{y:\mathbb{N} \Rightarrow (\lambda x^{\mathbb{N}}.x) \ y = y:\mathbb{N}} \text{ (Sym}_{\text{Elem}}\text{)}} \text{ (Context}_1\text{)} \\
 \\
 \frac{\frac{\frac{\frac{\mathbb{N}:\text{Set}}{y:\mathbb{N} \Rightarrow \text{Context}} \text{ (Context}_1\text{)}}{y:\mathbb{N} \Rightarrow y:\mathbb{N}} \text{ (Ass)}}{y:\mathbb{N} \Rightarrow y = (\lambda x^{\mathbb{N}}.x) \ y:\mathbb{N}} \text{ (Trans}_{\text{Elem}}\text{)}} \text{ (Context}_1\text{)} \\
 \\
 \frac{\frac{\frac{\frac{\mathbb{N}:\text{Set}}{y:\mathbb{N} \Rightarrow \text{Context}} \text{ (Context}_1\text{)}}{y:\mathbb{N} \Rightarrow y+0=(\lambda x^{\mathbb{N}}.x) \ y:\mathbb{N}} \text{ (N-Eq}_{+,0}\text{)}}{\lambda y^{\mathbb{N}}.y+0=\lambda y^{\mathbb{N}}.(\lambda x^{\mathbb{N}}.x) \ y:\mathbb{N} \rightarrow \mathbb{N}} \text{ (}\rightarrow\text{-I}^-\text{)}
 \end{array}$$

Example Deriv. (Gen. Equal. Rules)

- ▶ In the previous derivation, the most complicated step was:

$$\frac{y : \mathbb{N}, x : \mathbb{N} \Rightarrow x : \mathbb{N} \quad y : \mathbb{N} \Rightarrow y : \mathbb{N}}{y : \mathbb{N} \Rightarrow (\lambda x^{\mathbb{N}}.x) y = y : \mathbb{N}} (\rightarrow -\text{Eq})$$

- ▶ This is an example of the [equality rule for the non-dependent function set](#):

$$\frac{x : A \Rightarrow b : B \quad a : A}{(\lambda x^A.b) a = b[x := a] : B} (\rightarrow -\text{Eq})$$

with $A := B := \mathbb{N}$, $b := x$, $a := y$.

Therefore $b[x := a] = y$.

- ▶ This instance of the rule was weakened by an additional context $y : \mathbb{N}$.

Example Deriv. (Gen. Equal. Rules)

- Note that from the premises of that rule

$$\frac{y : \mathbb{N}, x : \mathbb{N} \Rightarrow x : \mathbb{N} \quad y : \mathbb{N} \Rightarrow y : \mathbb{N}}{y : \mathbb{N} \Rightarrow (\lambda x^{\mathbb{N}}.x) y = y : \mathbb{N}} (\rightarrow \text{-Eq})$$

we can derive using the introduction and elimination rule

$$y : \mathbb{N} \Rightarrow (\lambda x^{\mathbb{N}}.x) y : \mathbb{N}$$

as follows:

$$\frac{\frac{y : \mathbb{N}, x : \mathbb{N} \Rightarrow x : \mathbb{N}}{y : \mathbb{N} \Rightarrow \lambda x^{\mathbb{N}}.x : \mathbb{N} \rightarrow \mathbb{N}} (\rightarrow \text{-I}) \quad y : \mathbb{N} \Rightarrow y : \mathbb{N}}{y : \mathbb{N} \Rightarrow (\lambda x^{\mathbb{N}}.x) y : \mathbb{N}} (\rightarrow \text{-El})$$

Example Deriv. (Gen. Equ. Rules)

- ▶ The equality rule expresses how the function $\lambda x^{\mathbb{N}}.x$ applied to y is evaluated as follows:
 - ▶ We evaluate the body of the function (x) by setting for x the argument of the function (y).
 - ▶ This is the same as substituting in the body for x the argument of the function, i.e. y .
- ▶ This explains how the detour above of first introducing and then eliminating an expression can be reduced (namely to y or in general to $b[x := a]$).

Substitution Rules

The following rules can be weakly derived:

Substitution 1

$$\frac{\Gamma, x : A, \Gamma' \Rightarrow \theta \quad \Gamma \Rightarrow a : A}{\Gamma, \Gamma'[x := a] \Rightarrow \theta[x := a]} \text{ (Subst}_1\text{)}$$

($\Gamma'[x := a]$ is the result of substituting in Γ' all occurrences of x by a).

Substitution 2

$$\frac{\Gamma, x : A, \Gamma' \Rightarrow B : \text{Set} \quad \Gamma \Rightarrow a = a' : A}{\Gamma, \Gamma'[x := a] \Rightarrow B[x := a] = B[x := a'] : \text{Set}} \text{ (Subst}_2\text{)}$$

Substitution Rules

Substitution 3

$$\frac{\Gamma, x : A, \Gamma' \Rightarrow b : B \quad \Gamma \Rightarrow a = a' : A}{\Gamma, \Gamma'[x := a] \Rightarrow b[x := a] = b[x := a'] : B[x := a]} \text{ (Subst}_3\text{)}$$

Example Deriv. (Substitution)

$$\frac{
 \frac{
 \frac{\dots}{x:\mathbb{N}, y:\mathbb{N} \Rightarrow x:\mathbb{N}} \text{ (Ass)}
 \quad
 \frac{
 \frac{\dots}{x:\mathbb{N}, y:\mathbb{N} \Rightarrow y:\mathbb{N}} \text{ (Ass)}
 }{x:\mathbb{N}, y:\mathbb{N} \Rightarrow x + y:\mathbb{N}} \text{ (N-I}_+\text{)}
 \quad
 0:\mathbb{N}
 }{
 \frac{
 y:\mathbb{N} \Rightarrow 0 + y:\mathbb{N}
 }{\lambda y^{\mathbb{N}}. 0 + y:\mathbb{N} \rightarrow \mathbb{N}} \text{ (}\rightarrow\text{-I)}
 } \text{ (Subst}_1\text{)}$$

Example Deriv. 2 (Substitution)

$$\begin{array}{c}
 \dots \\
 \hline
 z:\mathbb{N}, x:\mathbb{N}, y:\mathbb{N} \Rightarrow x+y:\mathbb{N}
 \end{array}
 \quad
 \begin{array}{c}
 \frac{\frac{\frac{\mathbb{N}:\text{Set}}{z:\mathbb{N} \Rightarrow \text{Context}} (\text{Context}_1)}{z:\mathbb{N} \Rightarrow \mathbb{N}:\text{Set}} (\mathbb{N}\text{-F})}{z:\mathbb{N}, u:\mathbb{N} \Rightarrow \text{Context}} (\text{Context}_1) \\
 \frac{z:\mathbb{N}, u:\mathbb{N} \Rightarrow \text{Context}}{z:\mathbb{N}, u:\mathbb{N} \Rightarrow u:\mathbb{N}} (\text{Ass}) \\
 \frac{z:\mathbb{N}, u:\mathbb{N} \Rightarrow u:\mathbb{N}}{z:\mathbb{N}, u:\mathbb{N} \Rightarrow S \ u:\mathbb{N}} (\mathbb{N}\text{-I}_S)
 \end{array}
 \quad
 \begin{array}{c}

5 (c) The Nondependent Function Type and Product

5 (d) Structural Rules

5 (e) The Dependent Function Set and \forall

5 (f) The Dependent Product and \exists

5 (g) Derivations vs. Agda Code

5 (h) Presuppositions

5 (i) The Full Logical Framework

5 (e) The Dependent Function Set and \forall

- ▶ The dependent function set is similar to the non-dependent function set (e.g. $A \rightarrow B$), except that we allow that the second set to depend on an element of the first set.
- ▶ Notation: $(x : A) \rightarrow B$, for the set of functions f which map an element $a : A$ to an element of $B[x := a]$.
- ▶ In set-theoretic notation this is:

$$\begin{aligned} &\{f \mid f \text{ function} \\ &\quad \wedge \text{dom}(f) = A \\ &\quad \wedge \forall a \in A. f(a) \in B[x := a]\} \end{aligned}$$

Example (Dep. Function Set)

- ▶ Let Gender be the set of **genders**, informally written

$$\text{Gender} = \{\text{female}, \text{male}\} .$$

- ▶ In Agda, Gender would be defined by

```
data Gender : Set where
  female  : Gender
  male    : Gender
```

Example (Dep. Function Set)

- ▶ Let for $g : \text{Gender}$ the set

Name g

be the collection of **names of that gender**, e.g. informally written

- ▶ Name female = {jill, sara},
- ▶ Name male = {tom, jim}.

Example (Dep. Function Set)

- More formally, Name can be defined in Agda as follows:

```
data FemaleName : Set where
  jill   : FemaleName
  sara   : FemaleName
```

```
data MaleName : Set where
  tom    : MaleName
  jim    : MaleName
```

```
Name : Gender → Set
Name female = FemaleName
Name male   = MaleName
```

Example (Dep. Function Set)

► Define

$$\begin{aligned} \text{select} &: (g : \text{Gender}) \rightarrow \text{Name } g \\ \text{select female} &= \text{jill} \\ \text{select male} &= \text{tom} \end{aligned}$$

- select selects for every gender a name.
- select female will be an element of $\text{Name female} = (\text{Name } g)[g := \text{female}]$.
- It wouldn't make sense to say $(\text{select female}) : \text{Name } g$, without knowing what g is.

Example (Dep. Function Set)

- An attempt to define select s.t. select male is not in maleName, e.g.

select male = jill

or that select female is not in femaleName, e.g.

select female = tom

will result in a **type error**.

Example (Dep. Function Set)

- Note that for instance we **don't** have

$$\lambda g^{\text{Gender}}.\text{tom} : (g : \text{Gender}) \rightarrow \text{Name } g$$

since we **don't** have

$$(\lambda g^{\text{Gender}}.\text{tom}) \text{female} : \text{Name female}$$

Rules of the Dep. Funct. Set

Formation Rule

$$\frac{A : \text{Set} \quad x : A \Rightarrow B : \text{Set}}{(x : A) \rightarrow B : \text{Set}} (\rightarrow \text{-F})$$

Introduction Rule

$$\frac{x : A \Rightarrow b : B}{\lambda x^A. b : (x : A) \rightarrow B} (\rightarrow \text{-I})$$

Rules of the Dep. Funct. Set

Elimination Rule

$$\frac{f : (x : A) \rightarrow B \quad a : A}{f \ a : B[x := a]} (\rightarrow\text{-El})$$

Equality Rule

$$\frac{x : A \Rightarrow b : B \quad a : A}{(\lambda x^A. b) \ a = b[x := a] : B[x := a]} (\rightarrow\text{-Eq})$$

The η -Rule

The η -rule has a special status:

η -Rule

$$\frac{f : (x : A) \rightarrow B}{f = \lambda x^A. f \ x : (x : A) \rightarrow B} (\rightarrow -\eta)$$

- ▶ As before, the η -rule expresses that every element of $(x : A) \rightarrow B$ is of the form $\lambda x^A. \text{something}$.
- ▶ The η -rule cannot be derived, if the element in question is a variable.

Equality Versions of the above

Equality Version of the Formation Rule

$$\frac{A = A' : \text{Set} \quad x : A \Rightarrow B = B' : \text{Set}}{(x : A) \rightarrow B = (x : A') \rightarrow B' : \text{Set}} \quad (\rightarrow -F=)$$

Equality Version of the Introduction Rule

$$\frac{x : A \Rightarrow b = b' : B}{\lambda x^A. b = \lambda x^A. b' : (x : A) \rightarrow B} \quad (\rightarrow -I=)$$

Equality Version of the Elimination Rule

$$\frac{f = f' : (x : A) \rightarrow B \quad a = a' : A}{f \ a = f' \ a' : B[x := a]} \quad (\rightarrow -El=)$$

Non-Dep. Funct. Set as an Abbrev.

- The **non-dependent function set**

$$A \rightarrow B$$

can be regarded as an **abbreviation** for the **dependent function set**

$$(x : A) \rightarrow B ,$$

where B does not depend on x .

- As for the product one can see that the rules for the non-dependent function set are special cases of the rules for the dependent function set.

The Dep. Function Set in Agda

- ▶ We have seen that the non-dependent function set is written as $\mathbf{A} \rightarrow \mathbf{B}$ in Agda.
- ▶ The notation for the **dependent function set** is $(\mathbf{x} : \mathbf{A}) \rightarrow \mathbf{B}$.

The Dep. Function Set in Agda

- ▶ Elements of $(x : A) \rightarrow B$ are introduced as before by using
 - ▶ either λ -abstraction, i.e. we can define

$$\begin{aligned} f & : (x : A) \rightarrow B \\ f & = \lambda(x : A) \rightarrow b \end{aligned}$$

or shorter (if Agda – as in most cases – can work the type A of x)

$$\begin{aligned} f & : (x : A) \rightarrow B \\ f & = \lambda x \rightarrow b \end{aligned}$$

- ▶ Requires that $b : B$ depending on $x : A$.
- ▶ Note that the type B of b depends on $x : A$.

The Dep. Function Set in Agda

- ▶ or by writing

$$\begin{aligned} f & : (x : A) \rightarrow B \\ f\ x & = b \end{aligned}$$

depfunctionset.agda

The Dep. Function Set in Agda

- ▶ Elimination is application using the same notation as before.
 - ▶ E.g., if $f : (x : A) \rightarrow B$ and $a : A$, then $f\ a : B[x := a]$.

Abbreviations

- We can write

$$(n \ m : \mathbb{N}) \rightarrow A$$

instead of

$$(n : \mathbb{N}) \rightarrow (m : \mathbb{N}) \rightarrow A$$

$(x : A) \rightarrow \dots$ vs. $\lambda(x : A) \rightarrow \dots$

- ▶ Sometimes users of Agda (including the lecturer himself) confuse $(x : A) \rightarrow \dots$ and $\lambda(x : A) \rightarrow \dots$.
- ▶ Happens probably because of the similarity of both notions.
 - ▶ $(x : A) \rightarrow B$ is a set (or type).
 - ▶ the set/type of functions, mapping $x : A$ to an element of type B .
 - ▶ Therefore it makes sense to talk about $s : ((x : A) \rightarrow B)$.

$$(x : A) \rightarrow \dots \text{ vs. } \lambda(x : A) \rightarrow \dots$$

- ▶ $\lambda(x : A) \rightarrow t$ is a term.
 - ▶ the function, mapping an element $x : A$ to the element t .
 - ▶ It does not make sense to say s is an element of a function.
 - ▶ Correspondingly it does not make sense to talk about $s : (\lambda(x : A) \rightarrow t)$.
- ▶ $(\lambda(x : A) \rightarrow t)$ never occurs in a position where a set/type is required.
 - ▶ It therefore never occurs **on the right hand side of $:$** .
 - ▶ It does however make sense to talk about $(\lambda(x : A) \rightarrow t) : B$ for some set (or type) B .

Predicate Log. in Dep. Type Theo.

- ▶ We have already seen how to represent the propositional connectives and decidable atomic formulae in Agda and therefore as well in dependent type theory:

- ▶ Implication

$$A \rightarrow B$$

is represented as the nondependent function set

$$A \rightarrow B$$

- ▶ Conjunction

$$A \wedge B$$

is represented as one of the two versions of the product of A and B .

Predicate Log. in Dep. Type Theo.

- ▶ Disjunction will be introduced later (as the disjoint union).
- ▶ $\neg A$ has been introduced as $A \rightarrow \perp$.
- ▶ If $f : A_1 \rightarrow \cdots \rightarrow A_n \rightarrow \text{Bool}$ is a function, we can represent the predicate “ $f \ a_1 \ \cdots \ a_n$ is true” as

$$\text{Atom } (f \ a_1 \ \cdots \ a_n)$$

[Jump over next slide](#)

Predicate Log. in Dep. Type Theo.

- ▶ The definitions of $\neg A$, Atom rely on the rules for \perp , \top , Bool and Atom .
- ▶ They have been only introduced in the λ -calculus (and the rules for Atom have not been introduced at all), but not yet in the context of dependent type theory.
- ▶ They will be introduced in detail later.
- ▶ In this Subsect. we will deal mainly with the predicate calculus in Agda.
- ▶ Therefore an understanding of the rules as they occur in the λ -calculus (or in case of Atom an understanding of how to use it in Agda) suffices.
 - ▶ The rules of the typed λ -calculus can easily be translated into type theory.

Predicate Log. in Dep. Type Theo.

- ▶ We will investigate, how to represent universal and (in the next section) existential quantification in dependent type theory.
- ▶ Since we have many types, we have to write when using quantifiers explicitly the type, the bound variable is ranging over:

We write therefore

- ▶ $\forall x : A.B$ or $\forall x^A.B$ for
“for all x of type A , B holds”
(where B usually depends on x);
- ▶ $\exists x : A.B$ or $\exists x^A.B$ for
“there exists an x of type A , s.t. B holds”
(again B usually depends on x).

Universal Quantification

- ▶ $\forall x^A.B$ is true iff, for all $x : A$ there exists a proof of B (with that x).
- ▶ Therefore a proof of $\forall x^A.B$ is a **function, which takes an $x:A$ and computes an element of B** .
- ▶ Therefore the set of proofs of $\forall x^A.B$ is the set of functions, mapping an element $x : A$ to an element of B .
- ▶ This set is just the **dependent function set** $(x : A) \rightarrow B$.
- ▶ Therefore we can **identify** $\forall x^A.B$ with **$(x : A) \rightarrow B$** .

\forall in Agda

- ▶ $\forall x^A.B$ is represented by $(x : A) \rightarrow B$ in Agda.
 - ▶ Remember that $\forall x : A.B$ is another notation for $\forall x^A.B$.
- ▶ As an example,
 - ▶ we define a $<$ -operation on `Bool` using `ff < tt` is true and `b < b'` is false, otherwise.
 - ▶ Then we show $\forall x^{\text{Bool}}.\neg(x < x)$.
- ▶ See [exampleLessBool.agda](#).

Example (\forall , Cont.)

- First we define a Boolean valued less-than relation on `Bool` as follows:

$$_ < \text{Bool} _ : \text{Bool} \rightarrow \text{Bool} \rightarrow \text{Bool}$$

$$\text{ff} < \text{Bool} \text{ } b = b$$

$$\text{tt} < \text{Bool} _ = \text{ff}$$

- This means that `<Bool` has the following truth table:

<code><Bool</code>	<code>ff</code>	<code>tt</code>
<code>ff</code>	<code>ff</code>	<code>tt</code>
<code>tt</code>	<code>ff</code>	<code>ff</code>

Example (\forall , Cont.)

- ▶ Explanation of this definition:
 - ▶ If we identify `ff` with the number 0, `tt` with 1, then $b <_{\text{Bool}} b'$ means that for the corresponding numbers we have $b < b'$.
 - ▶ Especially we have:
 - ▶ if a is false, then a is less than b iff b is true, so the truth value of $a <_{\text{Bool}} b$ is the same as b .
 - ▶ if a is true, then a is never less than b .

\lt Boollong

$_ \lt \text{Bool} _ : \text{Bool} \rightarrow \text{Bool} \rightarrow \text{Bool}$

$\text{ff} \lt \text{Bool } b = b$

$\text{tt} \lt \text{Bool } _ = \text{ff}$

- The above defines the same function as the following long version:

$_ \lt \text{Boollong} _ : \text{Bool} \rightarrow \text{Bool} \rightarrow \text{Bool}$

$\text{ff} \lt \text{Boollong } \text{ff} = \text{ff}$

$\text{ff} \lt \text{Boollong } \text{tt} = \text{tt}$

$\text{tt} \lt \text{Boollong } \text{ff} = \text{ff}$

$\text{tt} \lt \text{Boollong } \text{tt} = \text{ff}$

$<$ Boollong

- ▶ Proving properties for $<$ Boollong is more complicated since the proof usually requires the same more complicated splitting up into cases.
- ▶ It is usually easier to proof properties for versions of functions, in which the number of case distinctions is reduced to a minimum.

Example (\forall , Cont.)

- Now we define $<$ as follows

$$\begin{aligned} _ < _ &: \text{Bool} \rightarrow \text{Bool} \rightarrow \text{Set} \\ b < b' &= \text{Atom } (b <_{\text{Bool}} b') \end{aligned}$$

Example (\forall , Cont.)

- We introduce \neg :

$$\begin{aligned}\neg &: \text{Set} \rightarrow \text{Set} \\ \neg A &= A \rightarrow \perp\end{aligned}$$

- The statement that $<$ is antireflexive is

$$\forall a^{\text{Bool}}. \neg(a < a)$$

which is represented in Agda as follows:

$$\begin{aligned}\text{Lemma4} &: \text{Set} \\ &= (a : \text{Bool}) \rightarrow \neg(a < a)\end{aligned}$$

Example (\forall , Cont.)

$$\begin{aligned} \text{Lemma4} & : \text{Set} \\ & = (a : \text{Bool}) \rightarrow \neg (a < a) \end{aligned}$$

► Since $\neg (a < a) = (a < a) \rightarrow \perp$, we have

$$\begin{aligned} \text{Lemma4} & = (a : \text{Bool}) \rightarrow \neg (a < a) \\ & = (a : \text{Bool}) \rightarrow (a < a) \rightarrow \perp \end{aligned}$$

Example (\forall , Cont.)

$$\text{Lemma4} = (a : \text{Bool}) \rightarrow (a < a) \rightarrow \perp$$

- ▶ We want to prove Lemma4.
 - ▶ A proof of Lemma4 will be an element
lemma4 : Lemma4.
- ▶ So we have to solve the following goal:

$$\begin{aligned} \text{lemma4} & : \text{Lemma4} \\ \text{lemma4} & = \{! \ !\} \end{aligned}$$

- ▶ The type of the goal is

$$\text{Lemma4} = (a : \text{Bool}) \rightarrow (a < a) \rightarrow \perp$$

Example (\forall , Cont.)

lemma4 : Lemma4

lemma4 = {! !}

Type of goal is Lemma4 = $(a : \text{Bool}) \rightarrow (a < a) \rightarrow \perp$.

- An element lemma4 : $(a : \text{Bool}) \rightarrow (a < a) \rightarrow \perp$ can be introduced by applying it to $a : A$ and $aa : a < a$:

lemma4 : Lemma4

lemma4 a aa = {! !}

- The type of goal is now the conclusion of $(a : \text{Bool}) \rightarrow (a < a) \rightarrow \perp$, namely \perp .

Example (\forall , Cont.)

lemma4 : Lemma4

lemma4 a $aa = \{! \ !\}$

Type of goal is \perp .

- ▶ We need to make use of our assumptions, namely $a : \text{Bool}$ and $aa : a < a$.
 - ▶ $a < b$ is defined by case disjunction on a and b .
 - ▶ Unless we know that $a = \text{tt}$ or $a = \text{ff}$, we don't know much about $a < a$.
 - ▶ So it seems to be a good step to make pattern matching using the cases $a = \text{tt}$ and $a = \text{ff}$.

Example (\forall , Cont.)

```
lemma4 : Lemma4
lemma4 ff aa = {! !}
lemma4 tt aa = {! !}
```

- The type of both goals is the same as before, namely \perp , since it didn't depend on a .

Example (\forall , Cont.)

lemma4 : Lemma4

lemma4 ff aa = {! !}

lemma4 tt aa = {! !}

- ▶ However, we know now more about the assumptions $aa : a < a$.
 - ▶ In case of $a = \text{ff}$, we have $aa : (a < a) = (\text{ff} < \text{ff}) = \perp$
 - ▶ So there is no case for $aa : \perp$, and we can solve this case by

lemma4 ff ()

Example (\forall , Cont.)

```
lemma4 : Lemma4
lemma4 ff ()
lemma4 tt aa = {! !}
```

- In case of $a = \text{tt}$, we have $aa : (a < a) = (\text{tt} < \text{tt}) = \perp$
 - Again we can solve this case by

```
lemma4 tt ()
```

We obtain the code

```
lemma4 : Lemma4
lemma4 ff ()
lemma4 tt ()
```

Example (\forall , Cont.)

- ▶ In the previous example,
 - ▶ the type of goal was \perp ,
 - ▶ and $aa : \perp$.
- ▶ So, instead of using case distinction on aa we could have as well inserted aa in those goals:

```
lemma4 : Lemma4
lemma4 ff aa = aa
lemma4 tt aa = aa
```

5 (a) Judgements

5 (b) Basic Form of Rules

5 (c) The Nondependent Function Type and Product

5 (d) Structural Rules

5 (e) The Dependent Function Set and \forall

5 (f) The Dependent Product and \exists

5 (g) Derivations vs. Agda Code

5 (h) Presuppositions

5 (i) The Full Logical Framework

5 (f) The Dependent Product and \exists

- ▶ The dependent product is similar as the non-dependent product (e.g. $A \times B$), except that we allow that the second set to depend on an element of the first set.
- ▶ The type theoretic notation is

$$(a : A) \times B$$

- ▶ Elements of $(a : A) \times B$ are pairs

$$\langle a', b' \rangle$$

s.t.

- ▶ $a' : A$
- ▶ $b' : B[a := a']$.

Example 1 (Dep. Products)

- ▶ One example for its use are the set of sorted lists:
 - ▶ Sorted l is a predicate on NatList expressing that l is sorted.
 - ▶ An element of

$$\text{SortedList} := (l : \text{NatList}) \times \text{Sorted } l$$

is a pair

$$\langle l, p \rangle$$

s.t.

- ▶ $l : \text{NatList}$,
 - ▶ $p : \text{Sorted } l$, i.e. p is a **proof** that l is sorted.
- ▶ So elements of SortedList are lists l together with a proof that l is sorted.

Example 2 (Dep. Products)

- ▶ Remember the Gender-example as in the last section:

- ▶ $\text{Gender} = \{\text{female}, \text{male}\}$.
- ▶ For $g : \text{Gender}$

$\text{Name } g$

is a collection of **names of that gender**, e.g. informally written

- ▶ $\text{Name female} = \{\text{jill}, \text{sara}\}$,
- ▶ $\text{Name male} = \{\text{tom}, \text{jim}\}$.

- ▶ The **set of names with their gender** is the set of pairs $\langle g, n \rangle$ s.t. g is a Gender and $n : \text{Name } g$.
- ▶ This set is written as

$$\text{NameWithGender} := (g : \text{Gender}) \times \text{Name } g$$

Rules of the Dependent Product

Formation Rule

$$\frac{A : \text{Set} \quad x : A \Rightarrow B : \text{Set}}{(x : A) \times B : \text{Set}} \quad (\times\text{-F})$$

Introduction Rule

$$\frac{x : A \Rightarrow B : \text{Set} \quad a : A \quad b : B[x := a]}{\langle a, b \rangle : (x : A) \times B} \quad (\times\text{-I})$$

Extra Premise in the Introd. Rule

- ▶ In the last introduction rule, an **extra premise** $x : A \Rightarrow B : \text{Set}$ was required.
 - ▶ This is required in order to guarantee that we can **form the set** $(x : A) \times B$.
 - ▶ In case of the non-dependent product, this premise was not necessary: $a : A$ and $b : B$ indirectly implies that we know $A : \text{Set}$ and $B : \text{Set}$, from which it follows $A \times B : \text{Set}$.

Example

- Assuming we have defined the set of genders $\text{Gender} : \text{Set}$ and the set of names $g : \text{Gender} \Rightarrow \text{Name } g : \text{Set}$, we can introduce the set

$$\text{NameWithGender} := (g : \text{Gender}) \times \text{Name } g : \text{Set}$$

by using the formation rule:

$$\frac{\text{Gender} : \text{Set} \quad g : \text{Gender} \Rightarrow \text{Name } g : \text{Set}}{(g : \text{Gender}) \times \text{Name } g : \text{Set}} (\times\text{-I})$$

Example

- Furthermore we can introduce

$$\langle \text{male}, \text{tom} \rangle : \text{NameWithGender}$$

as follows:

$$\frac{g : \text{Gender} \Rightarrow \text{Name } g : \text{Set} \quad \text{male} : \text{Gender} \quad \text{tom} : \text{Name male}}{\langle \text{male}, \text{tom} \rangle : (g : \text{Gender}) \times \text{Name } g} \quad (\times\text{-I})$$

- Note that we need the premise

$$g : \text{Gender} \Rightarrow \text{Name } g : \text{Set}$$

Otherwise we only know that $\text{Name male} : \text{Set}$, but not that $\text{Name female} : \text{Set}$.

[Jump to the elimination rules for the product.](#)

Example

- Note that we **don't** have

$$\langle \text{female}, \text{tom} \rangle : \text{NameWithGender}$$

since we **don't** have

$$\text{tom} : \text{Name female}$$

So here dependent types prevent errors. In an ordinary programming language without dependent types, we can't define a corresponding type `NameWithGender` which allows at compile time to define

$$\langle \text{male}, \text{tom} \rangle : \text{NameWithGender}$$

but not

$$\langle \text{female}, \text{tom} \rangle : \text{NameWithGender}$$

Rules of the Dependent Product

Elimination Rules

$$\frac{c : (x : A) \times B}{\pi_0(c) : A} (\times\text{-El}_0) \qquad \frac{c : (x : A) \times B}{\pi_1(c) : B[x := \pi_0(c)]} (\times\text{-El}_1)$$

Equality Rules

$$\frac{x : A \Rightarrow B : \text{Set} \quad a : A \quad b : B[x := a]}{\pi_0(\langle a, b \rangle) = a : A} (\times\text{-Eq}_0)$$

$$\frac{x : A \Rightarrow B : \text{Set} \quad a : A \quad b : B[x := a]}{\pi_1(\langle a, b \rangle) = b : B[x := a]} (\times\text{-Eq}_1)$$

Note that the last two rules require the extra premise $x : A \Rightarrow B : \text{Set}$ (which is not implied by the other premises).

Example

- In the “Name”-example we have that, if $a : \text{NameWithGender}$, then $\pi_0(a) : \text{Gender}$ and $\pi_1(a) : \text{Name } \pi_0(a)$:

$$\frac{a : (g : \text{Gender}) \times \text{Name } g}{\pi_0(a) : \text{Gender}} (\times\text{-El}_0)$$

$$\frac{a : (g : \text{Gender}) \times \text{Name } g}{\pi_1(a) : \text{Name } \pi_0(a)} (\times\text{-El}_1)$$

Example

► Furthermore

$$\pi_0(\langle \text{male}, \text{tom} \rangle) = \text{male} : \text{Gender}$$

therefore

$$\text{Name } \pi_0(\langle \text{male}, \text{tom} \rangle) = \text{Name male}$$

$$\pi_1(\langle \text{male}, \text{tom} \rangle) = \text{tom} : \text{Name } \pi_0(\langle \text{male}, \text{tom} \rangle)$$

therefore as well

$$\pi_1(\langle \text{male}, \text{tom} \rangle) = \text{tom} : \text{Name male}$$

Rules of the Dependent Product

We have the following **η -rule**:

$$\frac{c : (x : A) \times B}{c = \langle \pi_0(c), \pi_1(c) \rangle : (x : A) \times C} (\times\text{-}\eta)$$

- ▶ As before, the η -rule expresses that every element of $(x : A) \times B$ is of the form $\langle \text{something}_0, \text{something}_1 \rangle$.
- ▶ The η -rule cannot be derived, if the element in question is a variable.

Equality Versions of the above

Equality Version of the Formation Rule

$$\frac{A = A' : \text{Set} \quad x : A \Rightarrow B = B' : \text{Set}}{(x : A) \times B = (x : A') \times B' : \text{Set}} \quad (\times\text{-F}^=)$$

Equality Version of the Introduction Rule

$$\frac{x : A \Rightarrow B : \text{Set} \quad a = a' : A \quad b = b' : B[x := a]}{\langle a, b \rangle = \langle a', b' \rangle : (x : A) \times B} \quad (\times\text{-I}^=)$$

Equality Versions of the Elimination Rules

$$\frac{c = c' : (x : A) \times B}{\pi_0(c) = \pi_0(c') : A} \quad (\times\text{-El}_0^=) \quad \frac{c = c' : (x : A) \times B}{\pi_1(c) = \pi_1(c') : B[x := \pi_0(c)]} \quad (\times\text{-El}_1^=)$$

The Non-Dep. Product as an Abbrev.

- ▶ The non-dependent product $A \times B$ can now be seen as an **abbreviation** for $(x : A) \times B$ for some fresh variable x .
- ▶ Taking $A \times B$ as an abbreviation, we can see that the **rules for the non-dependent product are special cases of the rules for the dependent product.**

[Jump to the dependent product in Agda.](#)

The Non-Dep. Product as an Abbrev.

- ▶ More precisely this can be seen as follows:
 - ▶ From $A : \text{Set}$ and $B : \text{Set}$ we can derive $x : A \Rightarrow B : \text{Set}$ using the **weakening rule**.
 - ▶ Therefore the **premises of the formation rule for the non-dependent product imply** those of the **formation rule for the non-dependent product**.
 - ▶ From a derivation of $a : A$ we can derive $A : \text{Set}$ (we need the concept of presupposition for that, as introduced later).
 - ▶ Therefore the premises of the **introduction rule for the non-dependent product imply those of the dependent product**.
 - ▶ Similarly for the elimination, equality and η -rule.

The Dependent Product in Agda

- ▶ In Agda, the record type allows already dependencies of later sets on previous ones:
 - ▶ Assume $A : \text{Set}$, and $B : \text{Set}$, possibly depending on $a : A$.
 - ▶ Then we can form

```
record AB : Set where
  field
    a  : A
    b  : B
```

The Dependent Product in Agda

record AB : Set where
field

$a : A$

$b : B$

- Elements of AB can be introduced in the same way as before, i.e. if $a' : A$ and $b' : B[a := a']$ then we can form

$$\text{record } \{a : a'; b = b'\} : \text{AB} .$$

- Note that $b' : B[a := a']$, so the type of b' depends on a' .
- Furthermore, if $ab : \text{AB}$, then
 $\text{AB}.a \ ab : A$,
 $\text{AB}.b \ ab : B[a := \text{AB}.a \ ab]$.

dependentProduct1.agda

The Dependent Product in Agda

- ▶ The same applies to the dependent product using data.
 - ▶ Assume $A : \text{Set}$, and $B : \text{Set}$, possibly depending on $a : A$.
 - ▶ Then we can form

data $AB : \text{Set}$ where
 $\text{prod} : (a' : A) \rightarrow B[a := a'] \rightarrow AB$

- ▶ Elements of this set can be introduced in the same way as before, i.e. if $a' : A$ and $b' : B[a := a']$ then we can form

$\text{prod } a' b' : AB$.

- ▶ Note that $b' : B[a := a']$, so the type of b' depends on a' .

The Dependent Product in Agda

- Furthermore, we can define the projections:

$$\begin{aligned}\pi_0 &: AB \rightarrow A \\ \pi_0 (\text{prod } a \ b) &= a \\ \pi_1 &: (ab : AB) \rightarrow B[a := \pi_0 \ ab] \\ \pi_1 (\text{prod } a \ b) &= b\end{aligned}$$

dependentProduct2.agda

The “Name”-Example in Agda

► Remember:

```
data Gender : Set where
  female  : Gender
  male    : Gender
```

```
data FemaleName : Set where
  jill   : FemaleName
  sara   : FemaleName
```

```
data MaleName : Set where
  tom   : MaleName
  jim   : MaleName
```

The “Name”-Example in Agda

```
data MaleName : Set where
  tom   : MaleName
  jim   : MaleName
```

```
data FemaleName : Set where
  jill   : FemaleName
  sara   : FemaleName
```

```
Name : Gender → Set
Name male    = MaleName
Name female  = FemaleName
```

The “Name”-Example in Agda

- Now we define

```
record NameWithGender : Set where
  field
    gender  : Gender
    name    : Name gender
```

See [exampleAllNames.agda](#).

The “Name”-Example in Agda

- Note that we have

`record {gender = male; name = tom} : NameWithGender`

whereas we **don't** have

`record {gender = male; name = jill} : NameWithGender`

- This is different from the dependent record type which occurs for instance in Pascal or Ada, where the second example doesn't result in a type error.

Existential Quantification

- ▶ $\exists x^A.B$ is true iff there exists an $a : A$ such that $B[x := a]$ is true.
- ▶ Therefore a proof of $\exists x^A.B$ is a **pair $\langle a, p \rangle$ consisting of an element $a : A$ and a proof p of $B[x := a]$.**
- ▶ Therefore the set of proofs of $\exists x^A.B$ is the **dependent product $(x : A) \times B$.**
- ▶ We can **identify $\exists x^A.B$ with $(x : A) \times B$.**

\exists in Agda

- $\exists x^A.B$ is represented therefore in Agda by one of the two dependent products in Agda:

```
record Version1 : Set where
  field
```

```
    a  :  A
```

```
    b  :  B[x := a]
```

```
data Version2 : Set where
```

```
  exists : (a : A) → B[x := a] → Version2
```

- Here $B[x := a]$ is the result of substituting in B for x the variable a .

\exists in Agda

- A generic version, depending on $A : \text{Set}$ and $B : A \rightarrow \text{Set}$ can be defined as follows
(The symbol \exists can be obtained by typing in “\exists”):

```
record  $\exists$ r (A : Set) (B : A  $\rightarrow$  Set) : Set where
  field
    a  : A
    b  : B a
```

```
data  $\exists$ d (A : Set) (B : A  $\rightarrow$  Set) : Set where
  exists : (a : A)  $\rightarrow$  B a  $\rightarrow$   $\exists$ d A B
```

existentialQuantification.agda

Example (\exists)

- ▶ As an example,
 - ▶ we define negation $\neg \text{Bool}$ on Bool ,
 - ▶ define an equality $==$ on Bool ,
 - ▶ and show $\forall a^{\text{Bool}}. \exists b^{\text{Bool}}. a == \neg \text{Bool } b$.
- ▶ See [exampleproofproplogic11.agda](#).

Example (\exists , Cont.)

- ▶ $\neg\text{Bool}$ is defined as follows:

$$\neg\text{Bool} : \text{Bool} \rightarrow \text{Bool}$$

$$\neg\text{Bool} \text{ tt} = \text{ff}$$

$$\neg\text{Bool} \text{ ff} = \text{tt}$$

Example (\exists)

- ▶ A Boolean valued equality on `Bool` is defined as follows:

$$_ ==_{\text{Bool}} _ : \text{Bool} \rightarrow \text{Bool} \rightarrow \text{Bool}$$

$$\text{tt} ==_{\text{Bool}} b = b$$

$$\text{ff} ==_{\text{Bool}} b = \neg \text{Bool } b$$

- ▶ This corresponds to the following truth table:

$==_{\text{Bool}}$	ff	tt
ff	tt	ff
tt	ff	tt

Example (\exists)

- Then we define

$$\begin{aligned} _ == _ &: \text{Bool} \rightarrow \text{Bool} \rightarrow \text{Set} \\ b == b' &= \text{Atom } (b ==_{\text{Bool}} b') \end{aligned}$$

Example (\exists , Cont.)

- In order to introduce the statement mentioned above, we introduce first the formula $\exists b^{\text{Bool}}.a == \neg \text{Bool } b$ depending on $a : \text{Bool}$:

```
record Lemma5aux (a : Bool) : Set where
  field
    b      : Bool
    ab     : a == ¬Bool b
```

- The statement $\forall a^{\text{Bool}}.\exists b^{\text{Bool}}.a == \neg \text{Bool } b$ is now as follows:

```
Lemma5    : Set
Lemma5    = (a : Bool) → Lemma5aux a
```

Example (\exists , Cont.)

- ▶ A proof of Lemma5 is an element

$$\text{lemma5} : \text{Lemma5}$$

and we get the goal

$$\begin{array}{ll} \text{lemma5} & : \quad \text{Lemma5} \\ \text{lemma5} & = \quad \{! \quad !\} \end{array}$$

- ▶ The type of goal is

$$\text{Lemma5} = (a : \text{Bool}) \rightarrow \text{Lemma5aux } a$$

- ▶ This goal is solved by applying lemma5 to $a : \text{Bool}$.

Example (\exists , Cont.)

Lemma5 : Set

Lemma5 = $(a : \text{Bool}) \rightarrow \text{Lemma5aux } a$

- We get

lemma5 : Lemma5
 lemma5 a = $\{! \ !\}$

- The type of the goal is (in pseudo Agda syntax)

Lemma5aux a = record $\{b : \text{Bool}; ab : a == \neg \text{Bool } b\}$

Example (\exists , Cont.)

lemma5 : Lemma5

lemma5 a = {! !}

Type of goal is

record {b : Bool; ab : a == \neg Bool b}

- ▶ We cannot show this goal universally for all a directly.
 - ▶ We have to provide a different b depending on whether $a = \text{tt}$ or $a = \text{ff}$.
 - ▶ So we introduce pattern matching on whether $a = \text{tt}$ or $a = \text{ff}$.

Example (\exists , Cont.)

- We get

```
lemma5 : Lemma5  
lemma5 ff  =  {! !}  
lemma5 tt  =  {! !}
```

Example (\exists , Cont.)

lemma5 : Lemma5

lemma5 ff = {! !}

lemma5 tt = {! !}

- In case of $a = \text{ff}$, the type of goal is

$$\text{Lemma5aux ff} = \text{record } \{ \begin{array}{l} b : \text{Bool}; \\ ab : \text{ff} == \neg \text{Bool } b \end{array} \}$$

- This goal can be solved as follows

$$\text{lemma5 ff} = \text{record } \{ b = \text{tt}; ab = \text{true} \}$$

(Note that $(\text{ff} == \neg \text{Bool tt}) = \top$, so $\text{true} : (\text{ff} == \neg \text{Bool tt})$).

Example (\exists , Cont.)

lemma5 : Lemma5

lemma5 ff = record {b = tt; ab = true}

lemma5 tt = {! !}

- The second goal can be solved as follows

lemma5 tt = record {b = ff; ab = true}

- So we get the complete proof:

lemma5 : Lemma5

lemma5 ff = record {b = tt; ab = true}

lemma5 tt = record {b = ff; ab = true}

Complex Example

- ▶ We assume $A, B : \text{Set}$ and equality relations on A, B :

```

postulate  A      : Set
postulate  _==A_  : A → A → Set
postulate  B      : Set
postulate  _==B_  : B → B → Set

```

- ▶ We will introduce
 - ▶ the product AB of A and B
 - ▶ an equality $==AB$ on AB
 - ▶ and show that if $==A$ and $==B$ are symmetric, so is $==AB$.
- ▶ See [exampleProductEqual.agda](#).

Equality Sets

- ▶ $==A$ (and $==B$) could be decidable equalities,
 - ▶ i.e. $==A = \lambda(a, b : A) \rightarrow \text{Atom} (\text{eqboolA } a \ b)$,
where $\text{eqboolA} : A \rightarrow A \rightarrow \text{Bool}$,
- ▶ Or an undecidable equality.
 - ▶ E.g. the equality on $\mathbb{N} \rightarrow \mathbb{N}$ is in standard logic

$$f = g :\Leftrightarrow \forall n^{\mathbb{N}}. f(n) = g(n)$$

which reads in Agda as follows:

$$\begin{aligned} _ ==_{\mathbb{N} \rightarrow _} : (f \ g : \mathbb{N} \rightarrow \mathbb{N}) &\rightarrow \text{Set} \\ f ==_{\mathbb{N} \rightarrow _} g &= (n : \mathbb{N}) \rightarrow f \ n == g \ n \end{aligned}$$

where $==$ is the equality on \mathbb{N} .

Undecidable Equalities

- ▶ The last equality is undecidable, since in order to check whether $f \equiv_{\mathbb{N} \rightarrow} g$ holds we have to check **for all** $n : \mathbb{N}$ whether $f\ n = g\ n$ holds

Complex Example (Cont.)

- The formation of $AB = A \times B$ is straightforward:

data $_ \times _ (A\ B : \text{Set}) : \text{Set}$ where
 $p : A \rightarrow B \rightarrow A \times B$

$AB : \text{Set}$
 $AB = A \times B$

Complex Example (Cont.)

- ▶ We define the equality $==_{AB}$ on $A \times B$ as follows:
 - ▶ Assume $ab, ab' : A \times B$.
 - ▶ ab and ab' are equal, if their first projections are equal w.r.t. $==_A$ and their second projections are equal w.r.t. $==_B$.
 - ▶ So we get

$$\begin{aligned} & _ ==_{AB} _ : AB \rightarrow AB \rightarrow \text{Set} \\ & (p \ a \ b) ==_{AB} (p \ a' \ b') = (a ==_A a') \wedge (b ==_B b') \end{aligned}$$

Complex Example (Cont.)

- ▶ We introduce the formulae expressing that an equality on a set is symmetric.
- ▶ We define this generically depending on an arbitrary set A and an arbitrary equality $_{==}$ on A .
- ▶ It is the formula

$$\forall a, a' : A. a == a' \rightarrow a' == a$$

- ▶ The Agda code is as follows:

```
Sym : (A : Set) → (A → A → Set) → Set
Sym A _==_ = (a a' : A) → a == a' → a' == a
```

Specialisation of Sym

- We create instances of Sym for symmetry on A, B, AB:

$$\begin{aligned} \text{SymA} & : \text{Set} \\ \text{SymA} & = \text{Sym } A \text{ } _ == A _ \end{aligned}$$

$$\begin{aligned} \text{SymB} & : \text{Set} \\ \text{SymB} & = \text{Sym } B \text{ } _ == B _ \end{aligned}$$

$$\begin{aligned} \text{SymAB} & : \text{Set} \\ \text{SymAB} & = \text{Sym } AB \text{ } _ == AB _ \end{aligned}$$

Formulae vs. Proofs

- ▶ Note that $\text{Sym}A$ is the **statement** expressing that $==A$ is symmetric.
 - ▶ It is not a proof that $==A$ is symmetric.
 - ▶ We can define $\text{Sym}A$ independently of whether $==A$ is symmetric or not.
 - ▶ A proof that $==A$ is symmetric is **an element of $\text{Sym}A$** , i.e a term $\text{sym}A$ s.t.

$$\text{sym}A : \text{Sym}A$$

- ▶ Note that we don't have to show that $\text{Sym}A$ holds.
 - ▶ We have to show that if $\text{Sym}A$ and $\text{Sym}B$ hold, then $\text{Sym}AB$ holds as well.

Complex Example

- ▶ What we want to show is that SymA and SymB implies SymAB .
- ▶ So we need to solve

$$\begin{aligned} \text{symAB} &: \text{SymA} \rightarrow \text{SymB} \rightarrow \text{SymAB} \\ \text{symAB} &= \{! \ !\} \end{aligned}$$

- ▶ We apply symAB to elements $\text{symA} : \text{SymA}$, $\text{symB} : \text{SymB}$ and obtain

$$\begin{aligned} \text{symAB} &: \text{SymA} \rightarrow \text{SymB} \rightarrow \text{SymAB} \\ \text{symAB } \text{symA } \text{symB} &= \{! \ !\} \end{aligned}$$

Complex Example

$\text{symAB} : \text{SymA} \rightarrow \text{SymB} \rightarrow \text{SymAB}$
 $\text{symAB } \text{symA } \text{symB} = \{! \}$

- The type of the goal is SymAB which is

$$(ab \ ab' : AB) \rightarrow ab ==_{AB} ab' \rightarrow ab' ==_{AB} ab$$

- In order to solve the goal we apply $\text{symAB } \text{symA } \text{symB}$ to ab, ab' and $abab' : ab ==_{AB} ab'$. We obtain

$\text{symAB} : \text{SymA} \rightarrow \text{SymB} \rightarrow \text{SymAB}$
 $\text{symAB } \text{symA } \text{symB } ab \ ab' \ abab' = \{! \}$

Complex Example

$$\begin{aligned} \text{symAB} &: \text{SymA} \rightarrow \text{SymB} \rightarrow \text{SymAB} \\ \text{symAB } \text{symA } \text{symB } ab \ ab' \ abab' &= \{! \ !\} \end{aligned}$$

- ▶ The type of the goal is now $ab' ==_{AB} ab$.
- ▶ $ab' ==_{AB} ab$ is defined by pattern matching on ab and ab' . In order to show it we use the same pattern matching:

$$\begin{aligned} \text{symAB} &: \text{SymA} \rightarrow \text{SymB} \rightarrow \text{SymAB} \\ \text{symAB } \text{symA } \text{symB } (p \ a \ b) \ (p \ a' \ b') \ abab' &= \{! \ !\} \end{aligned}$$

Complex Example

$\text{symAB} : \text{SymA} \rightarrow \text{SymB} \rightarrow \text{SymAB}$

$\text{symAB } \text{symA } \text{symB } (p \ a \ b) \ (p \ a' \ b') \ abab' = \{! \ !\}$

- ▶ $abab' : a ==_A a' \wedge b ==_B b'$.

In order to obtain the two components $aa' : a ==_A a'$ and $bb' : b ==_B b'$, we apply pattern matching to $abab'$ as well.

- ▶ We obtain

$\text{symAB} : \text{SymA} \rightarrow \text{SymB} \rightarrow \text{SymAB}$

$\text{symAB } \text{symA } \text{symB } (p \ a \ b) \ (p \ a' \ b') \ (\text{and } aa' \ bb') = \{! \ !\}$

Complex Example

$\text{symAB} : \text{SymA} \rightarrow \text{SymB} \rightarrow \text{SymAB}$

$\text{symAB } \text{symA } \text{symB } (p \ a \ b) \ (p \ a' \ b') \ (\text{and } aa' \ bb') = \{! \ !\}$

- The Type of the goal is

$$(a' ==_A a) \wedge (b' ==_B b)$$

- Elements of it are of the form $p \ ab \ ab'$ with $a'a : a' ==_A a$ and $b'b : b' ==_B b$.
- So we insert into the goal p and use `intro`.
We obtain

$\text{symAB} : \text{SymA} \rightarrow \text{SymB} \rightarrow \text{SymAB}$

$\text{symAB } \text{symA } \text{symB } (p \ a \ b) \ (p \ a' \ b') \ (\text{and } aa' \ bb')$
 $= p \ \{! \ !\} \ \{! \ !\}$

Complex Example

$\text{symAB} : \text{SymA} \rightarrow \text{SymB} \rightarrow \text{SymAB}$
 $\text{symAB } \text{symA } \text{symB } (p \ a \ b) \ (p \ a' \ b') \ (\text{and } aa' \ bb')$
 $= p \ \{! \ !\} \ \{! \ !\}$

- ▶ The type of the first goal is $a' ==_A a$.
- ▶ We have $aa' : a ==_A a'$ and
 $\text{symA} : (a \ a' : A) \rightarrow a ==_A a' \rightarrow a' ==_A a$.
- ▶ So

$$\text{symA } a \ a' \ aa' : a' ==_A a$$

and this term can be used in order to solve the first goal:

$\text{symAB} : \text{SymA} \rightarrow \text{SymB} \rightarrow \text{SymAB}$
 $\text{symAB } \text{symA } \text{symB } (p \ a \ b) \ (p \ a' \ b') \ (\text{and } aa' \ bb')$
 $= p \ (\text{symA } a \ a' \ aa') \ \{! \ !\}$

Complex Example

```

symAB : SymA → SymB → SymAB
symAB symA symB (p a b) (p a' b') (and aa' bb')
  = p (symA a a' aa') {! !}

```

- ▶ The type of the second goal is $b' ==B b$ which can be solved by $\text{symB } b \text{ } b' \text{ } bb'$.
- ▶ We obtain

```

symAB : SymA → SymB → SymAB
symAB symA symB (p a b) (p a' b') (and aa' bb')
  = p (symA a a' aa') (symB b b' bb')

```

5 (g) Derivations vs. Agda Code

- ▶ In this subsection we look at the **relationship between Agda code and the corresponding derivations**.
 - ▶ We consider various examples.
 - ▶ **First** we will go through the development of the Agda code.
 - ▶ **Then** we will look at, how the corresponding derivations are developed, following each step in the development of the Agda code.

Example 1

- ▶ We want to derive in Agda

$$\lambda(a : A).a : A \rightarrow A$$

(See example file [exampleIdentity.agda](#))

- ▶ **Step 1:**

- ▶ We need to introduce the type A first.
- ▶ Since we want to have the definition for an arbitrary type A , we postulate (i.e. assume) one type A :

postulate $A : \text{Set}$

Example 1 (Cont.)

- **Step 2:** We state our goal:

$$\begin{aligned} f &: A \rightarrow A \\ f &= \{! \ !\} \end{aligned}$$

Example 1 (Cont.)

► Step 3:

- We want to derive an element of function type $A \rightarrow A$.
- Elements of the function type $A \rightarrow A$ are introduced by using **λ -terms**.
- If introduced as a λ -term, the term in question will be of the form **$\lambda(a : A) \rightarrow \text{something}$** .
- So we insert into the goal $\lambda(a : A) \rightarrow \{! \ !\}$, use **agda-give** and obtain

$$\begin{aligned} f &: A \rightarrow A \\ f &= \lambda(a : A) \rightarrow \{! \ !\} \end{aligned}$$

(The precise Agda code uses \backslash instead of λ , and \rightarrow instead of \rightarrow).

Example 1 (Cont.)

► Step 4:

- In order for $\lambda(a : A) \rightarrow \{! \ !\}$ to be of type $A \rightarrow A$, $\{! \ !\}$ must be of **type A**.
 - Then this λ -term computes an element of type A depending on some a of type A , which means it is a function of type $A \rightarrow A$.
 - So the type of the goal is A .
 - This can be inspected by using the goal menu
Goal type
 which shows the type of the current goal.
 - It has to be executed while the cursor is inside one goal.
 - It shows **A**.

Example 1 (Cont.)

► Step 4 (Cont.)

- We can inspect the context.
- The context contains as only element $a : A$.
 - Since we are defining a an element of type A depending on $a : A$, we can use a .

Example 1 (Cont.)

► Step 4 (Cont.)

- Now everything with result type A (i.e. which has at the right side of the arrow A) can be used in order to solve the goal.
 - f would result in black-hole recursion.
 - So we take a .
- We type in a into the goal and then use the command **Refine**
- We obtain:

$$\begin{aligned} f &: A \rightarrow A \\ &= \lambda(a : A) \rightarrow a \end{aligned}$$

and are done.

derivationsagdacode1.agda

Example 1, Using Rules

- ▶ In **Agda step 1** we postulated $A : \text{Set}$.
This corresponds to having the global assumption $A : \text{Set}$.
- ▶ In **Agda step 2** we stated our goal:

$$\begin{aligned} f &: A \rightarrow A \\ &= \{! \quad !\} \end{aligned}$$

In terms of rules this means that we want to derive something of type $A \rightarrow A$.

We write for this something d_0 and get as conclusion of our derivation:

$$d_0 : A \rightarrow A$$

Example 1, Using Rules (Cont.)

- In **Agda step 3** we replaced $\{! \ !\}$ by $\lambda(a : A) \rightarrow \{! \ !\}$:

$$\begin{aligned} f &: A \rightarrow A \\ &= \lambda(a : A) \rightarrow \{! \ !\} \end{aligned}$$

In terms of rules this means that we replace d_0 by $\lambda a^A.d_1$ which is derived by an introduction rule

$$\frac{a : A \Rightarrow d_1 : A}{\lambda a^A.d_1 : A \rightarrow A} (\rightarrow\text{-I})$$

Example 1, Using Rules (Cont.)

- In **Agda step 4** we replaced $\{! \ !\}$ in $\lambda(a : A) \rightarrow \{! \ !\}$ by a :

$$\begin{aligned} f &: A \rightarrow A \\ f &= \lambda(a : A) \rightarrow a \end{aligned}$$

In terms of rules this means that we replace d_1 by a .
 $a : A \Rightarrow a : A$ follows by an assumption rule:

$$\frac{a : A \Rightarrow a : A}{\lambda a^A. a : A \rightarrow A} (\rightarrow -I)$$

- The assumption rule will be discussed later.
 - Essentially it allows to derive if $x : B$ occurs in the context that $x : B$ holds.

Example 2

- ▶ We consider a derivation of

$$\lambda(a \rightarrow a : (A \rightarrow A) \rightarrow A). a \rightarrow a \ (\lambda(a : A) \rightarrow a) \\ : ((A \rightarrow A) \rightarrow A) \rightarrow A$$

(See example [exampleSampleDerivation2.agda](#)).

- ▶ **Step 1:**

- ▶ We postulate A :

postulate $A : \text{Set}$

- ▶ We state our goal:

$$f : ((A \rightarrow A) \rightarrow A) \rightarrow A \\ f = \{! \ !\}$$

Example 2 (Cont.)

► Step 2:

- The type of the goal is a function type.
We therefore insert into the goal $\lambda(a \rightarrow a : (A \rightarrow A) \rightarrow A) \rightarrow \{! \}$,
use goal command **Refine** and obtain
- We obtain

$$\begin{aligned} f &: ((A \rightarrow A) \rightarrow A) \rightarrow A \\ f &= \lambda(a \rightarrow a : (A \rightarrow A) \rightarrow A) \rightarrow \{! \} \end{aligned}$$

Example 2 (Cont.)

► Step 3:

- The type of the new goal is A , which is the result type of the function we are defining.
- The context contains $a-a-a : (A \rightarrow A) \rightarrow A$.
- We can as well use f (for recursive definitions) and A for solving the goal.
- $a-a-a$ is a function of result type A . Applying it to its argument would have as result an element of the type of the goal in question.

Example 2 (Cont.)

► Step 3 (Cont):

- Therefore we type into the goal $a-a-a$ and use goal command **Refine**.
 - Agda will then apply $a-a-a$ to as many goals as needed in order to obtain an element of the desired type.
In our case it is one (of type $A \rightarrow A$).
 - We obtain

$$f : ((A \rightarrow A) \rightarrow A) \rightarrow A$$

$$f = \lambda(a-a-a : (A \rightarrow A) \rightarrow A) \rightarrow a-a-a \{! \ !\}$$

Example 2 (Cont.)

► Step 4:

- The type of the new goal is $A \rightarrow A$.
 - This is since $a-a-a : (A \rightarrow A) \rightarrow A$ needs to be applied to an element of type $A \rightarrow A$ in order to obtain an element of type A .
 - An element of type $A \rightarrow A$ can be introduced by a λ -expression $\lambda(a : A) \rightarrow \{! \ !\}$.
 - We type this into the goal and use **Refine** and obtain:

$$f : ((A \rightarrow A) \rightarrow A) \rightarrow A$$

$$f = \lambda(a-a-a : (A \rightarrow A) \rightarrow A) \rightarrow a-a-a (\lambda(a : A) \rightarrow \{! \ !\})$$

Example 2 (Cont.)

► Step 5

- The new goal has type A .
 - The complete expression $\lambda(a : A) \rightarrow \{! \}$ should have type $A \rightarrow A$, so $\{! \}$ must have type A .
- The context contains $a-a-a$ and a ; we can use as well f , A .
 - Both $a-a-a$ and a have the correct result type A .
 - There is usually more than one solution for proceeding in Agda. This means that we sometimes have to backtrack and try a different solution.

Example 2 (Cont.)

► Step 5 (Cont.)

- We try $a : A$. After inserting it and using **Refine** we obtain the following and are done.

$$f : ((A \rightarrow A) \rightarrow A) \rightarrow A$$

$$f = \lambda(a-a-a : (A \rightarrow A) \rightarrow A) \rightarrow a-a-a (\lambda(a : A) \rightarrow a)$$

Example 2, Using Rules

- ▶ Postulating $A : \text{Set}$ corresponds to that we make a global assumption $A : \text{Set}$.
- ▶ Stating the goal means that we have as last line of the derivation:

$$d_0 : ((A \rightarrow A) \rightarrow A) \rightarrow A$$

- ▶ We will in the following use *aaa* instead of $a-a-a$ in order to save space in derivations.

Example 2, Using Rules

- ▶ The next step in the Agda-derivation was to replace the goal by $\lambda(aaa : (A \rightarrow A) \rightarrow A) \rightarrow \{! \ !\}$.
- ▶ This corresponds to replacing d_0 by $\lambda(aaa : (A \rightarrow A) \rightarrow A).d_1$ and having as last step an introduction rule:

$$\frac{aaa : (A \rightarrow A) \rightarrow A \Rightarrow d_1 : A}{\lambda aaa^{((A \rightarrow A) \rightarrow A)}.d_1 : ((A \rightarrow A) \rightarrow A) \rightarrow A} (\rightarrow\text{-I})$$

Example 2, Using Rules

- ▶ The next step in the Agda-derivation used `refine`.
`{! !}` was replaced by `aaa {! !}`.
- ▶ This corresponds to replacing d_1 by $aaa\ d_2$, and using one elimination rule in order to derive it:

$$\frac{\frac{aaa:(A \rightarrow A) \rightarrow A \Rightarrow aaa:(A \rightarrow A) \rightarrow A \quad aaa:(A \rightarrow A) \rightarrow A \Rightarrow d_2:A \rightarrow A}{aaa:(A \rightarrow A) \rightarrow A \Rightarrow aaa\ d_2:A} (\rightarrow\text{-El})}{\lambda aaa^{(A \rightarrow A) \rightarrow A}.aaa\ d_2:((A \rightarrow A) \rightarrow A) \rightarrow A} (\rightarrow\text{-I})$$

- ▶ The left top judgement can be derived by an **assumption rule** (more about this later).

Example 2, Using Rules

- ▶ We then used intro on the goal which was then replaced by $\lambda(a : A) \rightarrow \{! \ !\}$.
- ▶ This corresponds to replacing d_2 by $\lambda a^A.d_3$ which can be introduced by an introduction rule:

$$\frac{\frac{aaa:(A \rightarrow A) \rightarrow A \Rightarrow aaa:(A \rightarrow A) \rightarrow A \quad \frac{aaa:(A \rightarrow A) \rightarrow A, a:A \Rightarrow d_3:A}{aaa:(A \rightarrow A) \rightarrow A \Rightarrow \lambda a^A. d_3:A \rightarrow A} (\rightarrow\text{-I})}{aaa:(A \rightarrow A) \rightarrow A \Rightarrow aaa(\lambda a^A. d_3):A} (\rightarrow\text{-El})$$

$$\frac{aaa:(A \rightarrow A) \rightarrow A \Rightarrow aaa(\lambda a^A. d_3):A}{(\lambda a^{aaa^{(A \rightarrow A) \rightarrow A}.aaa})(\lambda a^A. d_3):((A \rightarrow A) \rightarrow A) \rightarrow A} (\rightarrow\text{-I})$$

Example 2, Using Rules

- ▶ Finally we used refine with a , which replaced the goal by a .
- ▶ This corresponds to replacing d_3 by a .

$$\frac{\frac{aaa:(A \rightarrow A) \rightarrow A \Rightarrow aaa:(A \rightarrow A) \rightarrow A \quad \frac{aaa:(A \rightarrow A) \rightarrow A, a:A \Rightarrow a:A}{aaa:(A \rightarrow A) \rightarrow A \Rightarrow \lambda a^A. a:A} (\rightarrow\text{-I})}{aaa:(A \rightarrow A) \rightarrow A \Rightarrow \lambda a^A. a:A} (\rightarrow\text{-El})$$

$$\frac{aaa:(A \rightarrow A) \rightarrow A \Rightarrow aaa(\lambda a^A. a):A}{(\lambda a^{aaa(A \rightarrow A) \rightarrow A}. aaa)(\lambda a^A. a):((A \rightarrow A) \rightarrow A) \rightarrow A} (\rightarrow\text{-I})$$

The right hand derivation can again be derived by an **assumption rule** (more about this later).

Example 3

- We derive an element of type

$$A \rightarrow B \rightarrow A \times B$$

(See [exampleProductIntro.agda](#)).

Example 3 (Cont.)

► Step 1:

- We postulate types A , B :

```
postulate A : Set
postulate B : Set
```

- We introduce the product type:

```
record _×_ (A B : Set) : Set where
  field
    first      : A
    second    : B
```

Example 3 (Cont.)

► **Step 2:**

- Our goal is:

$$\begin{aligned} f &: A \rightarrow B \rightarrow A \times B \\ f &= \{! \ !\} \end{aligned}$$

Example 3 (Cont.)

► Step 3:

- An element of $A \rightarrow B \rightarrow A \times B$ will be of the form

$$\lambda(a : A) \rightarrow \lambda(b : B) \rightarrow \{! \ !\}$$

- We insert this into our goal and use **Refine** and obtain

$$\begin{aligned} f &: A \rightarrow B \rightarrow A \times B \\ f &= \lambda(a : A) \rightarrow \lambda(b : B) \rightarrow \{! \ !\} \end{aligned}$$

Example 3 (Cont.)

► Step 4:

- The new goal is of type $A \times B$ which is a record type.
An element of it can be introduced by an introduction rule.
- Elements of type $A \times B$ introduced by the introduction principle will have the form

$$\begin{array}{rcl} \text{record } \{ \text{first} & = & \{! \ !\}; \\ & \text{second} & = \{! \ !\} \end{array}$$

Example 3 (Cont.)

► Step 4 (Cont):

- We insert this into the goal and obtain:

$$\begin{aligned}
 f &: A \rightarrow B \rightarrow A \times B \\
 &= \lambda(a : A) \rightarrow \lambda(b : B) \rightarrow \text{record } \{ \text{first} \quad = \quad \{! \ !\}; \\
 &\quad \quad \quad \text{second} \quad = \quad \{! \ !\} \}
 \end{aligned}$$

Example 3 (Cont.)

► Step 5:

- The first goal has as context:
 - $a : A$,
 - $b : B$
- We could use as well
 - $A, B : \text{Set}$,
 - $A \times B : \text{Set}$,
 - $f : A \rightarrow B \rightarrow A \times B$.

Example 3 (Cont.)

► Step 5 (Cont)

- We insert a , use refine and solve the first goal:

$$\begin{aligned}
 f &: A \rightarrow B \rightarrow A \times B \\
 f &= \lambda(a : A) \rightarrow \lambda(b : B) \rightarrow \text{record } \{ \text{first} \quad = \quad a; \\
 &\quad \text{second} \quad = \quad \{! \ !\} \}
 \end{aligned}$$

Example 3 (Cont.)

► Step 6:

- Similarly we can solve the second one:

$$\begin{aligned}
 f &: A \rightarrow B \rightarrow A \times B \\
 f &= \lambda(a : A) \rightarrow \lambda(b : B) \rightarrow \text{record } \left\{ \begin{array}{ll} \text{first} & = a; \\ \text{second} & = b \end{array} \right\}
 \end{aligned}$$

Example 3, Using Rules

- ▶ $A \times B$ is formed as follows (assuming the global assumptions $A : \text{Set}$, $B : \text{Set}$):

$$\frac{A : \text{Set} \quad B : \text{Set}}{A \times B : \text{Set}} (\times\text{-F})$$

- ▶ We won't use this however, since it is required for the assumption rules only, the treatment of which will be delayed until later.

Example 3, Using Rules (Cont.)

- ▶ Stating the goal corresponds to having as last line of the derivation:

$$d_0 : A \rightarrow B \rightarrow (A \times B)$$

- ▶ Using λ -abstraction means that we replace d_0 by $\lambda a^A.\lambda b^B.d_1$ which is introduced by two introduction rules:

$$\frac{a : A, b : B \Rightarrow d_1 : A \times B}{a : A \Rightarrow \lambda b^B.d_1 : B \rightarrow (A \times B)} (\rightarrow\text{-I})$$

$$\frac{a : A \Rightarrow \lambda b^B.d_1 : B \rightarrow (A \times B)}{\lambda a^A.\lambda b^B.d_1 : A \rightarrow B \rightarrow (A \times B)} (\rightarrow\text{-I})$$

Example 3, Using Rules (Cont.)

- The use of record is reflected by replacing d_1 by $\langle d_2, d_3 \rangle$, which can be introduced by an introduction rule:

$$\begin{array}{c}
 \frac{a : A, b : B \Rightarrow d_2 : A \quad a : A, b : B \Rightarrow d_3 : B}{a : A, b : B \Rightarrow \langle d_2, d_3 \rangle : A \times B} (\times\text{-I}) \\
 \frac{a : A \Rightarrow \lambda b^B. \langle d_2, d_3 \rangle : B \rightarrow (A \times B)}{\lambda a^A. \lambda b^B. \langle d_2, d_3 \rangle : A \rightarrow B \rightarrow (A \times B)} (\rightarrow\text{-I})
 \end{array}$$

Example 3, Using Rules (Cont.)

- Solving the goals by refining them with a , b means that we replace d_2 by b , d_3 by c :

$$\frac{
 \frac{
 \frac{
 a : A, b : B \Rightarrow a : A \quad a : A, b : B \Rightarrow b : B
 }{a : A, b : B \Rightarrow \langle a, b \rangle : A \times B} (\times\text{-I})
 }{a : A \Rightarrow \lambda b^B. \langle a, b \rangle : B \rightarrow (A \times B)} (\rightarrow\text{-I})
 }{\lambda a^A. \lambda b : B. \langle a, b \rangle : A \rightarrow B \rightarrow (A \times B)} (\rightarrow\text{-I})$$

- The premises require an assumption rule (which will use the derivation of $A \times B$), see later for details.

Example 4

- We derive an element of type

$$(A \rightarrow B \times C) \rightarrow A \rightarrow B$$

(See [exampleProductElim.agda](#)).

Example 4 (Cont.)

► Step 1:

- We postulate types A , B , C :

```
postulate A : Set
postulate B : Set
postulate C : Set
```

- The product is introduced as before:

```
record _×_ (A B : Set) : Set where
  field
    first      : A
    second     : B
```

Example 4 (Cont.)

► Step 2:

- Our goal is:

$$\begin{aligned} f &: (A \rightarrow B \times C) \rightarrow A \rightarrow B \\ f &= \{! \quad !\} \end{aligned}$$

Example 4 (Cont.)

► Step 3:

- We insert a λ -expression into the goal, **refine**, and obtain:

$$\begin{aligned} f &: (A \rightarrow B \times C) \rightarrow A \rightarrow B \\ f &= \lambda(a-bc : A \rightarrow B \times C) \rightarrow \lambda(a : A) \rightarrow \{! \quad !\} \end{aligned}$$

Example 4 (Cont.)

► Step 4:

- The context has no element with result type B .
- However, $a-bc$ has function type with result type $B \times C$, which can be projected to B .
- We introduce first an element of type $B \times C$ by a let-expression, and then derive from it the desired element of type B :

Example 4 (Cont.)

► Step 4 (Cont):

- We insert before the goal a let-expression and obtain:

$$\begin{aligned}
 f &: (A \rightarrow B \times C) \rightarrow A \rightarrow B \\
 f &= \lambda(a \text{--} bc : A \rightarrow B \times C) \\
 &\rightarrow \lambda(a : A) \\
 &\rightarrow \text{let } bc : B \times C \\
 &\quad bc = \{! \ !\} \\
 &\quad \text{in } \{! \ !\}
 \end{aligned}$$

Example 4 (Cont.)

► Step 5:

- For solving the first goal (definition of bc) we can refine $a-bc$, which has as result type $B \times C$.

$$\begin{aligned}
 f &: (A \rightarrow B \times C) \rightarrow A \rightarrow B \\
 f &= \lambda(a-bc : A \rightarrow B \times C) \\
 &\quad \rightarrow \lambda(a : A) \\
 &\quad \rightarrow \text{let } bc : B \times C \\
 &\quad \quad bc = a-bc \{! \ !\} \\
 &\quad \text{in } \{! \ !\}
 \end{aligned}$$

Example 4 (Cont.)

► Step 6:

- The new goal can be solved by refining it with variable a :

$$\begin{aligned}
 f &: (A \rightarrow B \times C) \rightarrow A \rightarrow B \\
 f &= \lambda(a-bc : A \rightarrow B \times C) \\
 &\rightarrow \lambda(a : A) \\
 &\rightarrow \text{let } bc : B \times C \\
 &\quad bc = a-bc\ a \\
 &\quad \text{in } \{! \ !\}
 \end{aligned}$$

Example 4 (Cont.)

► Step 7:

- The type of the new goal is B .
- We obtain from bc an element of this type, by applying the first projection to it.
 - This projection is $_{\times} \text{first}$.
- We obtain

$$\begin{aligned}
 f &: (A \rightarrow B \times C) \rightarrow A \rightarrow B \\
 f &= \lambda(a-bc : A \rightarrow B \times C) \\
 &\quad \rightarrow \lambda(a : A) \\
 &\quad \rightarrow \text{let } bc : B \times C \\
 &\quad \quad bc = a-bc\ a \\
 &\quad \text{in } _{\times} \text{first } bc
 \end{aligned}$$

Example 4 (Cont.)

- ▶ In our rule calculus we don't introduce a let construction (we could add this).
- ▶ In order to get close to the derivations, we omit in the Agda derivation the let expression, and replace in the body of it bc by its definition $(a-bc\ a)$.
- ▶ We get

$$\begin{aligned}
 f &: (A \rightarrow B \times C) \rightarrow A \rightarrow B \\
 f &= \lambda(a-bc : A \rightarrow B \times C) \\
 &\quad \rightarrow \lambda(a : A) \\
 &\quad \rightarrow _ \times _ \text{.first } (a-bc\ a)
 \end{aligned}$$

Example 4, Using Rules

- ▶ Using rules we make the global assumptions $A : \text{Set}, B : \text{Set}, C : \text{Set}$.
- ▶ Then we start with our goal

$$d_0 : (A \rightarrow (B \times C)) \rightarrow A \rightarrow B$$

Example 4, Using Rules (Cont.)

- The use of a λ -expression amounts to replacing d_0 by

$$\lambda a-bc^{A \rightarrow (B \times C)}. \lambda a^A. d_1$$

introduced by two applications of an introduction rule:

$$\frac{\frac{a-bc : A \rightarrow (B \times C), a : A \Rightarrow d_1 : A}{a-bc : A \rightarrow (B \times C) \Rightarrow \lambda a^A. d_1 : A \rightarrow B} (\rightarrow -I)}{\lambda a-bc^{A \rightarrow (B \times C)}. \lambda a^A. d_1 : (A \rightarrow (B \times C)) \rightarrow A \rightarrow B} (\rightarrow -I)$$

Example 4, Using Rules (Cont.)

- ▶ In Agda, we then replace the goal corresponding to d_1 by $_ \times _ \text{.first } (a - bc \ a)$.
- ▶ In our rule calculus, this reads $\pi_0(a - bc \ a)$.
- ▶ This can be introduced by two applications of elimination rules:

$$\begin{array}{c}
 \frac{a - bc : A \rightarrow (B \times C), a : A \Rightarrow a - bc : A \rightarrow (B \times C) \quad a - bc : A \rightarrow (B \times C), a : A \Rightarrow a : A}{\frac{\frac{\frac{a - bc : A \rightarrow (B \times C), a : A \Rightarrow a - bc \ a : B \times C}{a - bc : A \rightarrow (B \times C), a : A \Rightarrow \pi_0(a - bc \ a) : B} (\times\text{-El})}{a - bc : A \rightarrow (B \times C) \Rightarrow \lambda a^A. \pi_0(a - bc \ a) : A \rightarrow B} (\rightarrow\text{-I})} (\rightarrow\text{-El}) \\
 \frac{a - bc : A \rightarrow (B \times C) \Rightarrow \lambda a^A. \pi_0(a - bc \ a) : A \rightarrow B}{\lambda a - bc^A \rightarrow (B \times C). \lambda a^A. \pi_0(a - bc \ a) : (A \rightarrow (B \times C)) \rightarrow A \rightarrow B} (\rightarrow\text{-I})
 \end{array}$$

- ▶ The two initial judgements can be introduced by assumption rules.

5 (a) Judgements

5 (b) Basic Form of Rules

5 (c) The Nondependent Function Type and Product

5 (d) Structural Rules

5 (e) The Dependent Function Set and \forall

5 (f) The Dependent Product and \exists

5 (g) Derivations vs. Agda Code

5 (h) Presuppositions

5 (i) The Full Logical Framework

5 (h) Presuppositions

- ▶ In order to derive $x : A, y : B \Rightarrow C : \text{Set}$ we need to show:
 - ▶ $A : \text{Set}$.
 - ▶ $x : A \Rightarrow B : \text{Set}$
- ▶ So the judgement

$$x : A, y : B \Rightarrow C : \text{Set}$$

implicitly contains the judgements

$$A : \text{Set} ,$$

$$x : A \Rightarrow B : \text{Set} .$$

Presuppositions (Cont.)

- ▶ $A : \text{Set}$ and $x : A \Rightarrow B : \text{Set}$ are presuppositions of the judgement $x : A, y : B \Rightarrow C : \text{Set}$.

Presuppositions (Cont.)

- ▶ $A : \text{Set}$ and $B : \text{Set}$ are presuppositions of the judgement

$$A \rightarrow B : \text{Set} .$$

and of the judgement

$$A \times B : \text{Set} .$$

- ▶ The next slide shows the presuppositions of judgements.

Presuppositions

Judgement	Presuppositions
$\Gamma, x : A \Rightarrow \text{Context}$	$\Gamma \Rightarrow A : \text{Set}.$
$\Gamma \Rightarrow A : \text{Set}$	$\Gamma \Rightarrow \text{Context}$
$\Gamma \Rightarrow A = B : \text{Set}$	$\Gamma \Rightarrow A : \text{Set},$ $\Gamma \Rightarrow B : \text{Set}.$

Presuppositions

Judgement	Presuppositions
$\Gamma \Rightarrow a : A$	$\Gamma \Rightarrow A : \text{Set}.$
$\Gamma \Rightarrow a = b : A$	$\Gamma \Rightarrow a : A,$ $\Gamma \Rightarrow b : A.$

Presuppositions

Judgement	Presuppositions
$\Gamma \Rightarrow (x : A) \rightarrow B : \text{Set}$	$\Gamma, x : A \Rightarrow B : \text{Set}.$
$\Gamma \Rightarrow (x : A) \times B : \text{Set}$	$\Gamma, x : A \Rightarrow B : \text{Set}.$

Presuppositions

- Furthermore, **presuppositions of presuppositions** of

$$\Gamma \Rightarrow \theta$$

are as well presuppositions of

$$\Gamma \Rightarrow \theta .$$

Example of Presuppositions

- ▶ $x : A, y : B \Rightarrow a = b : (z : C) \times D$ **presupposes:**
 - ▶ $\emptyset \Rightarrow \text{Context},$
 - ▶ $A : \text{Set},$
 - ▶ $x : A \Rightarrow \text{Context},$
 - ▶ $x : A \Rightarrow B : \text{Set},$
 - ▶ $x : A, y : B \Rightarrow \text{Context},$
 - ▶ $x : A, y : B \Rightarrow C : \text{Set},$
 - ▶ $x : A, y : B, z : C \Rightarrow \text{Context},$
 - ▶ $x : A, y : B, z : C \Rightarrow D : \text{Set},$
 - ▶ $x : A, y : B \Rightarrow (z : C) \times D : \text{Set},$
 - ▶ $x : A, y : B \Rightarrow a : (z : C) \times D,$
 - ▶ $x : A, y : B \Rightarrow b : (z : C) \times D.$

Remark on $A \rightarrow B$, $A \times B$

- ▶ Note that $A \rightarrow B$ is an **abbreviation** for $(x : A) \rightarrow B$ for some fresh x .
- ▶ Similarly $A \times B$ is an **abbreviation** for $(x : A) \times B$ for some fresh x .
- ▶ Therefore the presupposition of $A \rightarrow B : \text{Set}$ (which abbreviates $\emptyset \Rightarrow A \rightarrow B : \text{Set}$) are:
 - ▶ $\emptyset \Rightarrow \text{Context}$,
 - ▶ $A : \text{Set}$,
 - ▶ $x : A \Rightarrow \text{Context}$,
 - ▶ $x : A \Rightarrow B : \text{Set}$.

5 (a) Judgements

5 (b) Basic Form of Rules

5 (c) The Nondependent Function Type and Product

5 (d) Structural Rules

5 (e) The Dependent Function Set and \forall

5 (f) The Dependent Product and \exists

5 (g) Derivations vs. Agda Code

5 (h) Presuppositions

5 (i) The Full Logical Framework

5 (i) The Full Logical Framework

- ▶ We would like to **add operations on types**, such as

$$\text{prod} : \text{Set} \rightarrow \text{Set} \rightarrow \text{Set}$$

which should take two sets and form the product of it.

- ▶ The problem is that for this we need

$$\text{Set} \rightarrow \text{Set} \rightarrow \text{Set} : \text{Set}$$

and our rules allow this only if we had

Set: Set

Set

- ▶ Adding

Set : Set

as a rule results however in an **inconsistent theory**:

- ▶ using this rule **we can prove everything**, especially false formulas.
The corresponding paradox is called Girard's paradox.

Jean-Yves Girard

Set (Cont.)

- ▶ Instead we introduce a **new level on top of Set called Type**.
 - ▶ So besides judgements $A : \text{Set}$ we have as well judgements of the form

$$A : \text{Type}$$

- ▶ One rule will especially express

$$\text{Set} : \text{Type}$$

- ▶ Elements of Type are **types**, elements of Set are **small types**.

Set (Cont.)

- ▶ We add rules asserting that **if $A : \text{Set}$ then $A : \text{Type}$** .
- ▶ Further we add rules asserting that Type is closed under the dependent function type and product.
- ▶ Since $\text{Set} : \text{Type}$ we get therefore (by closure under the function type)

$$\text{Set} \rightarrow \text{Set} \rightarrow \text{Set} : \text{Type}$$

and we can **assign to prod above the type**

$$\text{prod} : \text{Set} \rightarrow \text{Set} \rightarrow \text{Set}$$

(The definition of prod will be given later.)

Set and Type

Set (Cont.)

- ▶ However, we **cannot use prod in order to form the product of two sets**, ie. we cannot introduce

$$\text{prod Set Set} : \text{Set} ,$$

since $\text{Set} : \text{Set}$ does not hold.

Rules for Set (as an El. of Type)

Formation Rule for Set

$$\text{Set} : \text{Type} \quad (\text{SetIsType})$$

Every Set is a Type

$$\frac{A : \text{Set}}{A : \text{Type}} \quad (\text{Set2Type})$$

Closure of Type

- Further we add rules stating that Type is closed under the dependent function type and the dependent product:

Closure of Type under the dependent product

$$\frac{A : \text{Type} \quad x : A \Rightarrow B : \text{Type}}{(x : A) \times B : \text{Type}} (\times\text{-F}^{\text{Type}})$$

Closure of Type under the dependent function type

$$\frac{A : \text{Type} \quad x : A \Rightarrow B : \text{Type}}{(x : A) \rightarrow B : \text{Type}} (\rightarrow\text{-F}^{\text{Type}})$$

Nondependent Case

- A special case of the above rule is the closure under the non-dependent function type and product.
This rule can be derived (e.g. from the premises one can derive using the other rules the conclusion).

Closure of Type under the non-dependent product

$$\frac{A : \text{Type} \quad B : \text{Type}}{A \times B : \text{Type}} (\times\text{-F}^{\text{Type}})$$

Closure of Type under the non-dependent function type

$$\frac{A : \text{Type} \quad B : \text{Type}}{A \rightarrow B : \text{Type}} (\rightarrow\text{-F}^{\text{Type}})$$

Equality Versions of the Rules

Formation Rule for Set

$$\text{Set} = \text{Set} : \text{Type} \quad (\text{SetIsType}^-)$$

Every Set is a Type

$$\frac{A = B : \text{Set}}{A = B : \text{Type}} \quad (\text{Set2Type}^-)$$

Equality Versions of the Rules

Closure of Type under the dependent product

$$\frac{A = A' : \text{Type} \quad x : A \Rightarrow B = B' : \text{Type}}{(x : A) \times B = (x : A') \times B' : \text{Type}} (\times\text{-F}^{\text{=,Type}})$$

Closure of Type under the dependent function type

$$\frac{A = A' : \text{Type} \quad x : A \Rightarrow B = B' : \text{Type}}{(x : A) \rightarrow B = (x : A') \rightarrow B' : \text{Type}} (\rightarrow\text{-F}^{\text{=,Type}})$$

Similarly for the non-dependent versions of the above.

Definition of prod

- ▶ Now $\text{Set} \rightarrow \text{Set} \rightarrow \text{Set} : \text{Type}$.
- ▶ And we can derive

$$\begin{aligned} \text{prod} &:= \lambda(X, Y : \text{Set}). X \times Y \\ &: \text{Set} \rightarrow \text{Set} \rightarrow \text{Set} \end{aligned}$$

- ▶ We jump over the details. [Jump over the details.](#)

Context Rules

- ▶ The types in the contexts, which were before only elements of `Set`, can now be as well elements of `Type`.
- ▶ Therefore we need an additional context rule

$$\frac{\Gamma \Rightarrow A : \text{Type}}{\Gamma, x : A \Rightarrow \text{Context}} (\text{Context}_1^{\text{Type}})$$

Example: prod

We can now introduce **prod : Set → Set → Set**:

First we derive $X : \text{Set}, Y : \text{Set} \Rightarrow X : \text{Set}$:

$$\frac{\frac{\frac{\text{Set} : \text{Type}}{X : \text{Set} \Rightarrow \text{Context}} (\text{Context}_1)}{X : \text{Set} \Rightarrow \text{Set} : \text{Type}} (\text{SetIsType})}{X : \text{Set}, Y : \text{Set} \Rightarrow \text{Context}} (\text{Context}_1) \\ \frac{}{X : \text{Set}, Y : \text{Set} \Rightarrow X : \text{Set}} (\text{Ass})$$

Similarly we derive $X : \text{Set}, Y : \text{Set} \Rightarrow Y : \text{Set}$.

Example: prod (Cont.)

Now we can derive our desired judgement:

$$\begin{array}{c}
 \frac{X : \text{Set}, Y : \text{Set} \Rightarrow X : \text{Set} \quad X : \text{Set}, Y : \text{Set} \Rightarrow Y : \text{Set}}{X : \text{Set}, Y : \text{Set} \Rightarrow X \times Y : \text{Set}} (\times\text{-F}) \\
 \frac{\quad}{X : \text{Set} \Rightarrow \lambda Y^{\text{Set}}. X \times Y : \text{Set} \rightarrow \text{Set}} (\rightarrow\text{-I}) \\
 \frac{X : \text{Set} \Rightarrow \lambda Y^{\text{Set}}. X \times Y : \text{Set} \rightarrow \text{Set}}{\lambda(X, Y : \text{Set}). X \times Y : \text{Set} \rightarrow \text{Set} \rightarrow \text{Set}} (\rightarrow\text{-I})
 \end{array}$$

and define

$$\begin{aligned}
 \text{prod} &:= \lambda(X, Y : \text{Set}). X \times Y \\
 &: \text{Set} \rightarrow \text{Set} \rightarrow \text{Set}
 \end{aligned}$$

Set vs. Type in Agda

- ▶ In Agda Type will be written as Set1.
- ▶ Set can be written as well as Set0.
- ▶ In Agda, we don't have that if $A : \text{Set}$ then $A : \text{Set1}$.
 - ▶ Idea is that from A we can derive an (up to β -reduction) unique B s.t. $A : B$
- ▶ However we have in Agda.
 - ▶ Assume $A : \text{Set}$ or $A : \text{Set1}$.
 - ▶ Assume $x : A \Rightarrow B : \text{Set}$ or $x : A \Rightarrow B : \text{Set1}$.
 - ▶ Assume that we have at least one of $A : \text{Set1}$ or $x : A \Rightarrow B : \text{Set1}$.
 - ▶ Then $(x : A) \rightarrow B$, $(x : A) \times B : \text{Set1}$.
- ▶ So $(x : A) \rightarrow B$ and $(x : A) \times B$ belongs to the maximum type level of A and B .

Hierarchies of Types

- If one wants to form

$$\text{prod}' : \text{Type} \rightarrow \text{Type} \rightarrow \text{Type} ,$$

one needs to have a further level Kind above Type, s.t.

$$\text{Type} : \text{Kind} .$$

- Then

$$\text{Type} \rightarrow \text{Type} \rightarrow \text{Type} : \text{Kind} .$$

- In Agda Kind is written as Set2.

Hierarchy of Types (Set, Type, Kind)

Rules for Type as a Kind

Type is a Kind

$\text{Type} : \text{Kind}$

Every Type is a Kind

$$\frac{A : \text{Type}}{A : \text{Kind}} (\text{Type2Kind})$$

Closure of Kind

Closure of Kind under the dependent product

$$\frac{A : \text{Kind} \quad x : A \Rightarrow B : \text{Kind}}{(x : A) \times B : \text{Kind}} (\times\text{-F}^{\text{Kind}})$$

Closure of Kind under the dependent function type

$$\frac{A : \text{Kind} \quad x : A \Rightarrow B : \text{Kind}}{(x : A) \rightarrow B : \text{Kind}} (\rightarrow\text{-F}^{\text{Kind}})$$

Plus **equality versions** of the above rules.

[Jump over Context Rule.](#)

Context Rules

- Again, the context rules have to be expanded:

$$\frac{\Gamma \Rightarrow A : \text{Kind}}{\Gamma, x : A \Rightarrow \text{Context}} (\text{Context}_1^{\text{Kind}})$$

Definition of prod'

- Now we can define

$$\begin{aligned}\text{prod}' &:= \lambda(X, Y : \text{Type}). X \times Y \\ &: \text{Type} \rightarrow \text{Type} \rightarrow \text{Type}\end{aligned}$$

Hierarchies of Types (Cont.)

- ▶ This can be iterated further, forming
 $\text{Type} = \text{Type}_1, \text{Kind} = \text{Type}_2, \text{Type}_3, \text{Type}_4 \dots$
- ▶ So we have
 - ▶ $\text{Set} : \text{Type},$
 - ▶ $\text{Set} : \text{Type}_2, \text{Type} = \text{Type}_1 : \text{Type}_2,$
 - ▶ $\text{Set} : \text{Type}_3, \text{Type} = \text{Type}_1 : \text{Type}_3, \text{Type}_2 : \text{Type}_3,$
 - ▶ $\text{Set} : \text{Type}_4, \text{Type} = \text{Type}_1 : \text{Type}_4, \text{Type}_2 : \text{Type}_4, \text{Type}_3 : \text{Type}_4,$
 - ▶ etc.

Hierarchies of Types (Cont.)

- ▶ Agda has a hierarchy of types built in, written as Set_0 (which is Set), Set_1 (which is Type), Set_2 (in the rule calculus called Kind), Set_3 etc.
- ▶ Again we don't have for instance $\text{Set} : \text{Set}_2$.
- ▶ But $(x : A) \rightarrow B$, $(x : A) \times B$ belong to the maximum type level of A and B .

Hierarchy of Types (Set0, Set1, Set2, ...)

Changes To Presuppositions

- ▶ If we have the two type levels `Set` and `Type`, the presuppositions change.
- ▶ E.g. the presupposition of $\Gamma \Rightarrow a : A$ is no longer $A : \text{Set}$ but $A : \text{Type}$.
 - ▶ It might be that the derivation derives actually $A : \text{Set}$, but that implies $A : \text{Type}$.
 - ▶ But it might be that we can only derive $A : \text{Type}$.
- ▶ Therefore the presuppositions have to be changed as in the following table.

Presuppositions (with Set, Type)

Judgement	Presuppositions
$\Gamma, x : A \Rightarrow \text{Context}$	$\Gamma \Rightarrow A : \text{Type}.$
$\Gamma \Rightarrow A : \text{Set}$	$\Gamma \Rightarrow A : \text{Type}.$
$\Gamma \Rightarrow A : \text{Type}$	$\Gamma \Rightarrow \text{Context}.$

Presuppositions (with Set, Type)

Judgement	Presuppositions
$\Gamma \Rightarrow A = B : \text{Set}$	$\Gamma \Rightarrow A : \text{Set},$ $\Gamma \Rightarrow B : \text{Set},$ $\Gamma \Rightarrow A = B : \text{Type}.$
$\Gamma \Rightarrow A = B : \text{Type}$	$\Gamma \Rightarrow A : \text{Type},$ $\Gamma \Rightarrow B : \text{Type}.$
$\Gamma \Rightarrow a : A$	$\Gamma \Rightarrow A : \text{Type}.$

Presuppositions (with Set, Type)

Judgement	Presuppositions
$\Gamma \Rightarrow a = b : A$	$\Gamma \Rightarrow a : A,$ $\Gamma \Rightarrow b : A.$
$\Gamma \Rightarrow (x : A) \times B : \text{Set}$	$\Gamma \Rightarrow A : \text{Set},$ $\Gamma, x : A \Rightarrow B : \text{Set}.$
$\Gamma \Rightarrow (x : A) \times B : \text{Type}$	$\Gamma, x : A \Rightarrow B : \text{Type}.$

Presuppositions (with Set, Type)

Judgement	Presuppositions
$\Gamma \Rightarrow (x : A) \rightarrow B : \text{Set}$	$\Gamma \Rightarrow A : \text{Set},$ $\Gamma, x : A \Rightarrow B : \text{Set}.$
$\Gamma \Rightarrow (x : A) \rightarrow B : \text{Type}$	$\Gamma, x : A \Rightarrow B : \text{Type}.$

Changes To Presuppositions

- ▶ If we have more levels (Kind or Set*i*), then the presuppositions have to be changed again.
 - ▶ E.g., if we have levels Set, Type, Kind, the presupposition
 - ▶ of $\Gamma \Rightarrow A : \text{Set}$ is $\Gamma \Rightarrow A : \text{Type}$,
 - ▶ of $\Gamma \Rightarrow A : \text{Type}$ is $\Gamma \Rightarrow A : \text{Kind}$,
 - ▶ of $\Gamma \Rightarrow A : \text{Kind}$ is $\Gamma \Rightarrow \text{Context}$.
