We present a system called SMYTH for program sketching in a typed functional language whereby the concrete evaluation of ordinary assertions gives rise to input-output examples, which are then used to guide the search to complete the holes. The key innovation, called *live bidirectional evaluation*, propagates examples "backward" through partially evaluated sketches. Live bidirectional evaluation enables SMYTH to (a) synthesize recursive functions without trace-complete sets of examples and (b) specify and solve interdependent synthesis goals. Eliminating the trace-completeness requirement resolves a significant limitation faced by prior synthesis techniques when given partial specifications in the form of input-output examples.

Program Sketching with Live Bidirectional Evaluation

To assess the practical implications of our techniques, we ran several experiments on benchmarks used to evaluate MYTH, a state-of-the-art example-based synthesis tool. First, given expert examples (and no partial implementations), we find that SMYTH requires on average 66% of the number of expert examples required by MYTH. Second, we find that SMYTH is robust to randomly-generated examples, synthesizing many tasks with relatively few more random examples than those provided by an expert. Third, we create a suite of small sketching tasks by systematically employing a simple sketching strategy to the MYTH benchmarks; we find that user-provided sketches in SMYTH often further reduce the total specification burden (i.e. the combination of partial implementations and examples). Lastly, we find that Leon and Synquid, two state-of-the-art logic-based synthesis tools, fail to complete several tasks on which SMYTH succeeds.

1 INTRODUCTION

Program synthesis is closer than ever to making its way into the working programmer's toolbox. Synthesis techniques that operate on fine-grained logical specifications—such as Sketch [Solar-Lezama 2008], Rosette [Torlak and Bodik 2013], Leon [Kneuss et al. 2013], and Synquid [Polikarpova et al. 2016]—as well as techniques that operate on input-output examples—such as Escher [Albarghouthi et al. 2013], λ^2 [Feser et al. 2015] Myth [Osera and Zdancewic 2015], and "Myth2" [Frankle et al. 2016]—can synthesize a variety of challenging tasks, from subtle bit-manipulating computations in imperative languages to recursive functions over inductive datatypes in functional languages.

Authors' addresses: Justin Lubin, University of Chicago, USA, justinlubin@uchicago.edu; Nick Collins, University of Chicago, USA, nickmc@uchicago.edu; Cyrus Omar, University of Michigan, USA, comar@umich.edu; Ravi Chugh, University of Chicago, USA, rchugh@cs.uchicago.edu.

Fig. 1. A program sketch in SMYTH to "stutter" each element of a list n times. The desired solutions for the holes in replicate are [] for the Z branch and x:: replicate n'x for the S branch.

However, there remain commonplace program synthesis tasks that cannot be completed by state-of-the-art techniques. Figure 1 shows an incomplete program (a.k.a. "program sketch"), written in an ML-style functional language. The implementation of the stutter_n function itself—which is intended to "stutter" each element of a given list n times—is complete. However, it depends on an incomplete helper function replicate with holes (written??) denoting missing expressions that the programmer might hope to automatically synthesize. The two assert statements provide simple test cases that constrain the behavior of stutter_n. Because stutter_n applies replicate, these assertions indirectly constrain the holes in replicate as well. Unfortunately, the aforementioned synthesis techniques are not able to synthesize the desired hole completions shown in blue boxes in Figure 1. In what ways do the prior techniques fall short for this task?

Logic-Based Program Synthesis. LEON [Kneuss et al. 2013] and Synquid [Polikarpova et al. 2016] support sketching for richly-typed, general-purpose functional languages (as used in Figure 1). As pioneered in Sketch [Solar-Lezama 2008], Leon and Synquid are solver-based techniques that fill holes such that given specifications are satisfied. Both systems synthesize many challenging benchmarks involving complex data invariants, yet neither can complete the task in Figure 1.

The approach to synthesis and verification in Leon does not decompose the assert constraints on stutter_n into constraints on replicate, so the holes remain unspecified. By using an approach based on *liquid types* [Rondon et al. 2008; Vazou et al. 2013], Synouid is able to systematically decompose the given constraints into the following specification:

```
replicate :: (n : Nat) \rightarrow (x : Nat)

\rightarrow { out : NatList | (n = 1 \land x = 0 \Rightarrow out = [0])

\land (n = 1 \land x = 1 \Rightarrow out = [1])

\land (n = 2 \land x = 3 \Rightarrow out = [3, 3]) }
```

However, because this specification is not inductive—it provides no information about replicate 0 0, replicate 0 1, replicate 1 3, or replicate 0 3—Synouid cannot type check the desired solution for replicate, let alone synthesize it.

Evaluator-Based Program Synthesis. In contrast to logic-based techniques, another class of techniques operate on input-output examples and rely on concrete evaluation to "guess-and-check" candidate terms. We choose the term *evaluator-based* to describe such techniques—rather than *example-based* or *programming-by-example*—to distinguish how the underlying algorithms work (using concrete evaluation) from the specification mechanism they provide to users (examples). Examples can also be encoded as partial logical specifications, as just discussed.

Among evaluator-based techniques, Escher [Albarghouthi et al. 2013] and MYTH [Osera and Zdancewic 2015] can synthesize recursive functions, and MYTH employs several type-directed

optimizations to navigate the search space. (We discuss the remaining systems in §7.) However, there are two fundamental reasons why these tools cannot complete the task in Figure 1.

Limitation A: Trace-Complete Examples. The user must provide input-output examples for recursive calls internal to the eventual solution—this is the "example analog" to Synquid's requirement for inductive logical specifications. Osera and Zdancewic [2015] acknowledge that providing trace-complete examples (i.e. serving as an oracle [Albarghouthi et al. 2013]) "proved to be difficult initially" even for experts, and "discovering ways to get around this restriction … would greatly help in converting this type-directed synthesis style into a usable tool." Miltner et al. [2020] also observe the need to "manage Myth's requirement for trace completeness."

Limitation B: Independent, Top-Level Goals. The user must factor all synthesis tasks into completely unimplemented top-level functions, each of which must be equipped directly with (trace-complete) example sets. The system attempts to synthesize each of these functions separately. Granular sketching, where holes appear in arbitrary positions and are simultaneously solved, is not supported.

Our Approach: Live Bidirectional Evaluation. In this paper, we present a new evaluator-based synthesis technique that addresses Limitations A and B. Holes can appear in arbitrary expression positions and are constrained by types and assert statements which give rise to example constraints. Given the sketch in Figure 1, our implementation—called SMYTH—synthesizes the desired expressions to fill the holes. (Our exposition employs certain syntactic conveniences not currently implemented. These are described in §5.)

In order to make evaluator-based synthesis techniques compatible with sketching, we must formulate hole-aware notions of (1) *concrete evaluation* and (2) *example satisfaction*—which form the central term enumeration search strategy (i.e. *guess-and-check*) for evaluator-based synthesis. Our solution, called *live bidirectional evaluation*, comprises two parts:

- (1) A live evaluator $e \Rightarrow r$ that partially evaluates a sketch e by proceeding around holes, producing a result r which is either a value or a "paused" expression that, when the necessary holes are filled, will "resume" evaluating; and
- (2) A live unevaluator $r \Leftarrow ex \dashv K$ that, given a result r to be checked against example ex, computes constraints K (over possibly many holes in the sketch) that, if satisfied, ensure the result will eventually produce a value satisfying ex.

Live evaluation is adapted from Omar et al. [2019] to our setting and is not a technical contribution of our work. Live unevaluation is the key novel mechanism that—together with live evaluation—enables us to "combine sketching with MYTH-style synthesis" (hence the name SMYTH). Compared to the aforementioned logic-based and other symbolic evaluation techniques (e.g. [Bornholt and Torlak 2018; Feng et al. 2017a; Wang et al. 2020]), live bidirectional evaluation employs *concrete* evaluation to collect example constraints "globally" across multiple holes in the sketch.

Contributions. This paper generalizes the theory of MYTH [Osera and Zdancewic 2015]—the state-of-the-art in type-directed, evaluator-based program synthesis—to support sketches and live bidirectional evaluation. Formally, we present a calculus of recursive functions, algebraic datatypes, and holes—called Core Smyth—which includes the following technical contributions:

• We present *live unevaluation*, a novel technique that checks example satisfaction of sketches. The combination of *live evaluation* to partially evaluate sketches [Omar et al. 2019] and live unevaluation—which we call *live bidirectional evaluation*—forms a core guess-and-check strategy for programs with holes. Our formulation generalizes MYTH, but the notion of live bidirectional evaluation can also be developed for other evaluator-based synthesizers. (§3.5)

• We use live bidirectional evaluation to simplify program assertions into input-output constraints and generalize the Myth hole synthesis algorithm to employ live bidirectional evaluation. The resulting synthesis algorithm (a) alleviates the trace-completeness requirement and (b) globally solves the examples that arise from multiple interdependent tasks. (§4)

For simplicity, our formal system accounts only for top-level asserts, but we describe how subsequent work may extend our approach to allow assertions in arbitrary program positions.

To empirically evaluate our approach, we implement SMYTH and perform several experiments:

- We synthesize 38 of 43 tasks from the MYTH benchmark suite [Osera 2015; Osera and Zdancewic 2015] in SMYTH. Given expert examples (without sketches), SMYTH requires 66% of the number of expert examples required by MYTH. Moreover, SMYTH typically requires only a slightly larger set of examples if they are generated randomly, rather than by an expert. (§ 6.2)
- To create a suite of sketching tasks, we identify a simple base case sketching strategy and apply it systematically to the MYTH benchmarks. As expected, base case sketches further reduce the number of examples that SMYTH requires to complete many tasks. Furthermore, the total specification size with sketching (partial implementation plus examples) is often smaller than without (just examples). (§6.3)
- We identify a handful of additional sketching tasks, similar in size and flavor to stutter_n, which SMYTH can complete. (§2)
- To situate our experimental results in a broader context, we run Leon and Synquid on our benchmarks. We find several tasks for which SMYTH succeeds but these tools do not. (§6.4)

The experimental results demonstrate (i) that the theoretical advances in SMYTH address Limitations A and B of prior evaluator-based synthesizers, and (ii) that even though examples can generally be encoded as logical specifications, current logic-based synthesizers are not necessarily strictly more powerful than evaluator-based ones.

Because our approach generalizes MYTH, we provide comparison throughout the paper. We further discuss related work in §7. Additional definitions, proofs, and experimental data are available in an extended technical report [Lubin et al. 2020]; in the rest of the paper, we write §A, §B, and §C to refer to appendices in the technical report.

2 OVERVIEW

In this section, we work through several small programs to introduce how SMYTH: (1) employs live bidirectional evaluation to check example satisfaction of guessed expressions (which, in our formulation, may include holes) ($\S 2.1$); (2) supports user-defined sketches ($\S 2.2$); and (3) derives examples from asserts in the program ($\S 2.3$).

We write holes $??_h$ below with explicit names h; our implementation automatically generates names for holes as in Figure 1. Literals 0, 1, 2, etc. are syntactic sugar for the corresponding naturals of type Nat = $Z \mid S$ Nat. Some judgement forms below are simplified for expositional purposes.

2.1 Synthesis without Trace-Completeness

Consider the task to synthesize plus given the three test cases on the right. Given this specification, the resulting *example constraint* $K_0 = (- \vdash \bullet_0 \models \{0 \ 1 \rightarrow 1, \ 2 \ 0 \rightarrow 2, \ 1 \ 2 \rightarrow 3\})$ requires that ??₀ (hole name 0 generated for the definition of plus) be filled with a function expression that, in the empty environment, –, conforms to the given input-output examples. (We write \bullet_h to distinguish the concrete syntax of constraints from expression holes ??_h.)

```
plus : Nat -> Nat -> Nat
plus = ??

assert (plus 0 1 == 1)
assert (plus 2 0 == 2)
assert (plus 1 2 == 3)
```

Given a set of constraints K_h , SMYTH employs the *hole synthesis* search procedure $K_h \leadsto e_h \dashv K'$ to fill the hole $??_h$ with an expression e_h that is valid assuming new constraints K' over other holes in the program. Following MYTH [Osera and Zdancewic 2015], hole synthesis begins with a guess-and-check approach that enumerates increasingly large terms comprising variables and functions applied to variables. This naïve search is limited to small terms, i.e., starting with AST size 1 in early "stages" of the search and increasing to size 13 in latter stages. When enumerative search fails to find a solution in a particular stage, hole synthesis performs *example-directed refinement and branching*: introductory forms and case analyses are considered, and the examples are *distributed* to create subgoals for new holes that arise.

We will describe the following search path—among many that SMYTH will consider—that yields the solution fix plus λm n -> case m of $\{Z \rightarrow n; S m' \rightarrow S \text{ (plus m' n)}\}\$ for plus.

First, because the goal is a function type, SMYTH synthesizes a recursive function literal, with subgoal $??_1$ for the body. The constraint set K_1 (not shown) consists of three constraints created from the three input-output examples in K_0 by binding the input values to m and n in the environment and constraining the new subgoal with the corresponding output value.

Second, after guessing-and-checking fails to solve $??_1$, SMYTH attempts to *branch* by guessing the scrutinee m. This scrutinee is evaluated in each environment of the three constraints in K_1 . One constraint from K_1 is distributed to subgoal $??_2$ for the base case branch (this constraint $K_{2.1}$ is shown below), and the other two constraints from K_1 are distributed to subgoal $??_3$ for the recursive case (these constraints K_3 are not shown).

Third, SMYTH chooses to work on the recursive branch, for which the two constraints in K_3 involve output examples 2 and 3 (i.e. S (S Z) and S (S (S Z))). SMYTH *refines* the task by synthesizing the literal S ??4; the new subgoal is constrained by two examples (in K_4 , shown below) obtained by removing the shared constructor head S from the output examples in K_3 . (SMYTH synthesizes a literal of the form S (S ??4) along other search paths, but those paths do not yield a solution as quickly as the one being described.)

```
\begin{split} K_{2.1} &= ((\texttt{plus} \mapsto ..., \texttt{m} \mapsto \texttt{0}, \texttt{n} \mapsto \texttt{1} \qquad) \vdash \bullet_2 \models \texttt{1}) \\ K_{4.1} &= ((\texttt{plus} \mapsto ..., \texttt{m} \mapsto \texttt{2}, \texttt{n} \mapsto \texttt{0}, \texttt{m'} \mapsto \texttt{1}) \vdash \bullet_4 \models \texttt{1}) \\ K_{4.2} &= ((\texttt{plus} \mapsto ..., \texttt{m} \mapsto \texttt{1}, \texttt{n} \mapsto \texttt{2}, \texttt{m'} \mapsto \texttt{0}) \vdash \bullet_4 \models \texttt{2}) \end{split}
```

The remaining two subgoals, ??4 and ??2, are filled via guess-and-check as discussed below.

Live Bidirectional Example Checking. To decide whether a guessed expression e conforms to a constraint $(E \vdash \bullet_h \models ex)$ in SMYTH, the procedure $Ee \Rightarrow r$ applies the substitution (i.e. environment) E to the expression and evaluates it to a result r, and the *live unevaluation* procedure $r \Leftarrow ex \dashv K$ checks satisfaction modulo new constraints K.

Consider guesses to fill ??₄. Notice that plus—the function Smyth is working to synthesize—is recursive and thus bound in the constraint environments above. In addition to variables and calls to existing functions, Smyth enumerates structurally-decreasing recursive calls (plus m' n, plus m n', and plus m' n').

When considering plus m' n, the name plus binds the following value comprising the first three fillings and the "current" guess:

```
fix plus (\lambda m \text{ n. case m } \{Z \rightarrow ??_2; S m' \rightarrow S \text{ (plus m' n)}\})
```

Given the environment in constraint $K_{4,1}$, the guess evaluates and unevaluates as follows:

```
plus m'n \to^* plus 1 0

\to^* S (plus 0 0)

\Rightarrow S ([(plus \mapsto ..., m \mapsto 0, n \mapsto 0)] ??<sub>2</sub>) \Leftarrow 1 + K_{2.2}
```

(We write $e \to^* e' \Rightarrow r$ to display intermediate steps of the big-step evaluation, but $e \to^* e'$ does not appear in the formal system.) Although the function is incomplete, *live evaluation* [Omar et al. 2019] resolves two recursive calls to plus, before the hole ??₂ in the base case reaches evaluation position; the resulting *hole closure*, of the form [E]??_h, captures the environment at that point. Comparing the result to 1 (i.e. S Z), unevaluation removes an S from each side and creates a new constraint $K_{2,2}$ (shown below) for the base case.

Similarly, the guess checks against constraint $K_{4,2}$, adding another new constraint $K_{2,3}$ (shown below) on the base case.

```
plus m' n \rightarrow^* plus 0 2

\Rightarrow [(plus \mapsto ..., m \mapsto 0, n \mapsto 2)]??_2 \leftarrow 2 \dashv K_{2.3}
```

Both checks succeed, so the fourth step of the search commits to the guess, returning the two new constraints in K_2' .

$$K_{2.2} = ((\text{plus} \mapsto ..., \text{m} \mapsto 0, \text{n} \mapsto 0) \vdash \bullet_2 \models 0)$$

 $K_{2.3} = ((\text{plus} \mapsto ..., \text{m} \mapsto 0, \text{n} \mapsto 2) \vdash \bullet_2 \models 2)$

The fifth and final step is to fill the base case $??_2$, subject to constraints $K_{2.1}$, $K_{2.2}$, and $K_{2.3}$. The guess n evaluates to the required values (0, 1, and 2, respectively), without assumption. Together, the five filled holes comprise the final solution.

Notice that the test cases used to synthesize plus were *not* trace-complete: live bidirectional example checking recursively called plus 1 0, plus 0 0, and plus 0 2, none of which were included in the examples. Instead, Smyth *generated* additional constraints that the user would be required to provide in prior systems (i.e. Escher, Myth, Myth2, and Synquid).

2.2 User-Defined Sketches

SMYTH is the first evaluator-based synthesis technique to support sketching, thus allowing users to split domain knowledge naturally across a partial implementation and examples. For instance, if the user sketches the zero cases for max, as shown in Figure 2, just a few examples are sufficient for SMYTH to complete the recursive case. (The library function spec2 asserts input-output examples for a binary function, as was written out fully for plus above.)

Sketches from the user are handled in the same way as the sketches, described above, created internally by the Smyth algorithm. Myth and several other evaluator-based techniques (cf. §7) can also be described as creating sketches internally, but Smyth uniquely supports *concrete evaluation* of sketches—with holes in arbitrary positions—as a way to generate new example constraints.

2.3 Deriving Examples from Assertions

For the plus and max programs so far, evaluating assertions provided examples "directly" on holes. In general, however, an assertion may involve more complicated results.

```
= m
                                          odd n =
            Ζ
                                                                  unJust mx =
max
    m
    Ζ
                                            case n of
                                                                    case mx of
max
            n
                  = n
\max (S m') (S n') = S (\max m' n')
                                              7
                                                      -> False
                                                                      Nothing -> 0
                                              S Z
                                                      -> True
                                                                      Just x -> x
                                              S S n'' -> odd n''
spec2 max
  [(1, 1, 1), (1, 2, 2), (3, 1, 3)]
                                          assert (odd (unJust Just 1 ) == True)
minus (S a') (S b') = minus a' b'
                                          mult p q =
minus a
              b
                                            case p of
                                              Z -> Z
                                              S p' -> plus q (mult p' q)
spec2 minus
  [(2, 0, 2), (3, 2, 1), (3, 1, 2)]
                                          spec2 mult
                                            [(2, 1, 2), (3, 2, 6)]
```

Fig. 2. Smyth fills the holes ?? (not shown) with the code shown in blue boxes.

For instance, consider the definitions of odd : Nat -> Bool and unJust : MaybeNat -> Nat in Figure 2, and the evaluation of the expression odd (unJust ??₅):

```
odd (unJust ??_5) \rightarrow^* odd (unJust ([-] ??_5))

\rightarrow^* odd (case ([-] ??_5) un \mathcal{J}ust)

\Rightarrow case (case ([-] ??_5) un \mathcal{J}ust) odd
```

(For clarity, we omit the recursive environment bindings for odd and unJust.) First, evaluation produces the hole closure [-]??5, which is passed to unJust. Then, the case expression in unJust—we write *unJust* to refer to its two branches—scrutinizes the hole closure. The form of the constructor application has not yet been determined, so evaluation "pauses" by returning the *indeterminate* [Omar et al. 2019] result case ([-]??5) *unJust*, which records the fact that, when the scrutinee resumes to a constructor head Nothing or Just, evaluation of the case will proceed down the appropriate branch. This indeterminate case result is passed to the odd function. Finally, the case inside odd—we write *odd* to refer to its three branches—scrutinizes it, building up a nested indeterminate result.

How can we "indirectly" constrain the expression $??_5$ to ensure that the partially evaluated expression case (case ($[-]??_5$) unfust) odd evaluates to True as asserted?

Unevaluating Case Expressions. Unevaluation will run each of the three branches of *odd* "in reverse," attempting to reconcile each with the required example, True; we write (1), (2), (3), etc. to help discuss different branches of the search considered by SMYTH:

```
\mathsf{case}\;(\mathsf{case}\;([-]\,??_5)\;\mathit{un}\; \mathit{Just})\;\mathit{odd}\;\; \leftarrow \;\; \mathsf{True} \;\; \dashv \;\; \textcircled{1}\, \textcircled{2}\, \textcircled{3}
```

- (1) The first branch expression, False, is inconsistent with True (i.e. False \Leftarrow True \neq).
- 2 The second branch expression, True, is equal to the example. However, to take this branch, unevaluation must ensure that the scrutinee—an indeterminate case result itself—will match the pattern S Z (i.e. 1); that is, case ([−]??₅) unfust ← 1 → (2a)(2b).
 - (2a) The first branch expression, 0, is inconsistent with 1.
 - (2b) Reasoning about the second branch expression is more involved: the variable x must bind the argument of Just, but we have not yet ensured that this branch will be taken! To bridge the gap, we bind x to the symbolic, and indeterminate, *inverse constructor application*

Just ⁻¹ ([–]??₅) when evaluating the branch expression; unevaluation "transfers" the resulting example from the symbolic result to the scrutinee:

$$x \Rightarrow Just^{-1}([-]??_5) \Leftarrow 1 + (-+ \bullet_5 \models Just 1)$$

This constraint ensures that the case in unJust will resolve to the second branch (Just x) and that its expression will produce 1, and thus that the case in odd will resolve to the second branch (S Z) and produce True, as asserted.

③ By recursively unevaluating the third branch, odd n'', case unevaluation can derive additional solutions: Just 3, Just 5, etc. Naïvely unevaluating all branches, however, would introduce a significant degree of non-determinism—even non-termination. Therefore, our formulation and implementation impose simple restrictions—described in §3 and §5—on case unevaluation to trade expressiveness for performance.

Altogether, live bidirectional evaluation untangles the interplay between indeterminate branching and assertions so that Smyth can, for instance, fill the holes in minus and mult in Figure 2.

3 LIVE BIDIRECTIONAL EVALUATION

In this section, we formally define live evaluation E; $F \vdash e \Rightarrow r$ and live unevaluation $F \vdash r \Leftarrow ex \dashv K$ for a calculus called Core Smyth. We choose a natural semantics (big-step, environment-style) presentation [Kahn 1987], though our techniques can be re-formulated for a small-step, substitution-style model. Compared to our earlier notation, here we refer to environments E and E—often typeset in light gray, because environments would "fade away" in a substitution-style presentation.

Our formulation proceeds as follows. First, in $\S 3.1$ and $\S 3.2$, we define the syntax and type checking judgements of Core Smyth. Next, in $\S 3.3$, we present live evaluation, which adapts the *live programming with holes* technique [Omar et al. 2019] to our setting; minor differences are described in $\S 7.1$. Lastly, we define example satisfaction in $\S 3.4$ and live unevaluation in $\S 3.5$. In $\S 4$, we build a synthesis pipeline around the combination of live evaluation and unevaluation.

3.1 Syntax

Figure 3 defines the syntax of Core Smyth, a calculus of recursive functions, unit, pairs, and (named, recursive) algebraic datatypes. We say "products" to mean unit and pairs.

Datatypes. We assume a fixed datatype context Σ . A datatype D has some number n of constructors C_i , each of which carries a single argument of type T_i —the type of C_i is $T_i \to D$.

Expressions and Holes. The expression forms on the first three lines are standard function, product, and constructor forms, respectively. The expressions $prj_1 e$ and $prj_2 e$ project the first and second components of a pair. Each case expression has one branch for each of the n constructors C_i corresponding to the type of the scrutinee e; for simplicity, nested patterns are not supported.

Holes $??_h$ can appear anywhere in expressions (i.e. expressions are sketches). We assume each hole in a sketch has a unique name h, but we sometimes write ?? when the name is not referred to. Hole contexts Δ define a *contextual type* ($\Gamma \vdash \bullet : T$) to describe the type and the type context that is available to expressions that can "fill" a given hole [Nanevski et al. 2008; Omar et al. 2019].

Results. We define a separate grammar of *results* r—with evaluation environments E that map variables to results—to support the definition of big-step, environment-style evaluation $E \vdash e \Rightarrow r$ below. Because of holes, results are not conventional values. Terminating evaluations produce two kinds of *final* results; neither kind of result is stuck (i.e. erroneous).

The four result forms on the first line of the result grammar would—on their own—correspond to values in a conventional natural semantics (without holes). In CORE SMYTH, these *determinate* results

can be eliminated in a type-appropriate position; the appendix (§ A.1) defines a simple predicate r det to identify such results, and type checking is discussed below. Note that a recursive function closure [E] fix $f(\lambda x.e)$ stores an environment E that binds the free variables of the function body e, except the name f of the function itself. We sometimes write $\lambda x.e$ for non-recursive functions.

The four *indeterminate* result forms on the second line of the grammar are unique to the presence of holes. Rather than aborting evaluation with an error when a hole reaches elimination position (e.g., raise "Hole"), an indeterminate result r (defined by the predicate r indet (§A.1)) serves as a placeholder for where to continue evaluation if and when the hole is later filled (either by the programmer or synthesis engine) with a well-typed expression. The primordial indeterminate result is a *hole closure* [E]?? $_h$ —the environment binds the free variables that a hole-filling expression may refer to. An indeterminate application r_1 r_2 appears when the function has not yet evaluated to a function closure (i.e. r_1 indet); we require that r_2 be final in accordance with our eager evaluation semantics, discussed below. An indeterminate projection $prj_{i \in [2]} r$ appears when the argument has not yet evaluated to a pair (i.e. r indet). An indeterminate case closure [E] case r of $\{C_i x_i \rightarrow e_i\}_{i \in [n]}$ appears when the scrutinee has not yet evaluated to a constructor application (i.e. r indet)—like with function and hole closures, the environment E is used when evaluation resumes with the appropriate branch. Because they record how "paused" expressions should "resume," we sometimes refer to indeterminate results as "partially evaluated expressions."

The *inverse constructor application* form C^{-1} r on the third line of the result grammar is internal to live unevaluation and is discussed in §3.5.

Fig. 3. Syntax of Core Smyth.

Examples. A synthesis goal $(\Gamma \vdash \bullet_h : T \models X)$ describes a hole $??_h$ to be filled according to the contextual type $(\Gamma \vdash \bullet : T)$ and *example constraints X*. Each example constraint $(E \vdash \bullet \models ex)$ requires that an expression to fill the hole must, in the environment E, satisfy example ex.

Examples include *simple values* v, which are first-order product values or constructor applications; *input-output* examples $\{v \to ex\}$, which constrain function-typed holes; and $top \top$, which imposes no constraints. We sometimes refer to example constraints simply as "examples" when the meaning is clear from context. The coercion $\lfloor v \rfloor$ "upcasts" a simple value to a result. The coercion $\lceil r \rceil = v$ "downcasts" a result to a simple value, if possible.

Examples are essentially the same as described by Osera and Zdancewic [2015]. SMYTH additionally includes top examples. For simplicity Core Smyth includes only first-order function examples, though our implementation (§ 5) supports higher-order function examples like Myth.

3.2 Type Checking

Type checking Σ ; Δ ; $\Gamma \vdash e : T$ (Figure 4) takes a hole type context Δ as input, used by the T-Hole rule to decide valid typings for a hole $??_h$. The remaining rules are standard (§ A.2).

3.3 Live Evaluation

Figure 4 defines *live evaluation* E; $F \vdash e \Rightarrow r$, which first uses *expression evaluation* $E \vdash e \Rightarrow r$ to produce a final result r, and then *resumes* evaluation $F \vdash r \Rightarrow r'$ of the result r in positions that were paused because of holes now filled by F.

Expression Evaluation. Compared to a conventional natural semantics, there are four new rules—E-Hole, E-App-Indet, E-Prj-Indet, and E-Case-Indet—one for each indeterminate result form. The E-Hole rule creates a hole closure [E]??_h that captures the evaluation environment.

The other three rules, suffixed "-INDET," are counterparts to rules E-App, E-Prj, and E-Case for determinate forms. For example, when a function evaluates to a result r_1 that is not a function closure, the E-App-Indet rule creates the indeterminate application result r_1 r_2 . The remaining

Type Checking (excerpt from §A.2) and Live Eval.

$$\Sigma; \Delta; \Gamma \vdash e : T \mid E; F \vdash e \Rightarrow r$$

$$\frac{\Delta(??_h) = (\Gamma \vdash \bullet : T)}{\sum ; \Delta ; \Gamma \vdash ??_h : T} \qquad \frac{E \vdash e \Rightarrow r \quad F \vdash r \Rightarrow r'}{E ; F \vdash e \Rightarrow r'}$$

Expression Evaluation (excerpt from §A.3)

$$E \vdash e \Rightarrow r$$

$$\begin{array}{c} E\text{-APP} \\ E \vdash e_1 \Rightarrow r_1 \quad E \vdash e_2 \Rightarrow r_2 \\ r_1 = [E_f] \text{ fix } f \ (\lambda x.e_f) \\ E \vdash ??_h \Rightarrow [E] ??_h \end{array} \begin{array}{c} E \vdash e_1 \Rightarrow r_1 \quad E \vdash e_2 \Rightarrow r_2 \\ E_f, \ f \mapsto r_1, \ x \mapsto r_2 \vdash e_f \Rightarrow r \\ E \vdash e_1 \ e_2 \Rightarrow r \end{array} \begin{array}{c} [E\text{-APP-INDET}] \\ E \vdash e_1 \Rightarrow r_1 \quad E \vdash e_2 \Rightarrow r_2 \\ r_1 \neq [E_f] \text{ fix } f \ (\lambda x.e_f) \\ E \vdash e_1 \ e_2 \Rightarrow r_1 \quad r_2 \end{array}$$

Resumption (excerpt from § A.4)

$$F \vdash r \Rightarrow r'$$

$$\frac{F(h) = e_h \quad E \vdash e_h \Rightarrow r \quad F \vdash r \Rightarrow r'}{F \vdash [E] ??_h \Rightarrow r'} \qquad \frac{h \notin dom(F) \quad F \vdash E \Rightarrow E'}{F \vdash [E] ??_h \Rightarrow [E'] ??_h}$$

Fig. 4. Type Checking, Evaluation, and Resumption.

Proc. ACM Program. Lang., Vol. 4, No. ICFP, Article 109. Publication date: August 2020.

rules are similar (§A.3). Evaluation is deterministic and produces final results; the appendix (§A.3) formally establishes these propositions, as well as a suitable notion of type safety.

Resumption. Result resumption resembles expression evaluation. For closures [E] ?? $_h$ over holes that F fill with an expression e_h , R-Hole-Resume evaluates e_h in the closure environment, producing a result r. Because e_h may refer to other holes now filled by F, r is recursively resumed to r'.

3.4 Example Satisfaction

Live evaluation partially evaluates a sketch to a result, and Figure 5 defines what it means for a result to satisfy an example. To decide whether expression e satisfies example constraint ($E \vdash \bullet \models ex$), the SAT rule evaluates the expression to a result r and then checks whether r satisfies ex. The XS-Top rule accepts all results. The remaining rules break down input-output examples (XS-INPUT-OUTPUT) into equality checks for products and constructors (XS-Unit, XS-Pair, and XS-Ctor).

Hole closures may appear in a satisfying result, but they may *not* be directly checked against product, constructor, or input-output examples. The purpose of *live unevaluation* is to provide a notion of example *consistency* to accompany this "ground-truth" notion of example satisfaction.

3.5 Live Unevaluation

Figure 6 defines *live unevaluation* $F \vdash r \Leftarrow ex \dashv K$, which produces constraints K over holes that are sufficient to ensure example satisfaction $F \vdash r \models ex$. The *live bidirectional example checking* judgement $F \vdash e \rightleftharpoons X \dashv K$ lifts this notion to example constraints: Live-Check appeals to evaluation followed by unevaluation to check each constraint in X.

THEOREM (SOUNDNESS OF LIVE UNEVALUATION).

If
$$F \vdash r \Leftarrow ex \dashv K$$
 and $F \oplus F' \models K$ and $F \oplus F' \vdash r \Rightarrow r'$, then $F \oplus F' \vdash r' \models ex$.

THEOREM (SOUNDNESS OF LIVE BIDIRECTIONAL EXAMPLE CHECKING).

If
$$F \vdash e \rightleftharpoons X \dashv K$$
 and $F \oplus F' \models K$, then $F \oplus F' \vdash e \models X$.

Example Constraint Satisfaction

$$F \vdash e \models X$$

$$\frac{\{E_i; F \vdash e \Rightarrow r_i \quad F \vdash r_i \models ex_i\}^{i \in [n]}}{F \vdash e \models \{(E_i \vdash \bullet \models ex_i)\}^{i \in [n]}}$$

Example Satisfaction

$$F \vdash r \models ex$$

Unevaluation Constraint Satisfaction

 $F \models K$

$$\frac{F \supseteq F_0 \qquad \{F \vdash ??_{h_i} \models X_i\}^{i \in [n]}}{F \models ((h_1 \mapsto X_1, \dots, h_n \mapsto X_n); F_0)}$$

Fig. 5. Example and Constraint Satisfaction.

Unevaluation Constraints. Two kinds of constraints K are generated by unevaluation (cf. Figure 3). The first is a context U of bindings $h \mapsto X$ that maps unfilled holes $??_h$ to sets X of example constraints ($E \vdash \bullet \models ex$). The second is a hole-filling F which, as discussed below, is used to optimize unevaluation of case expressions. The former are "hole example contexts," analogous to hole type contexts Δ ; the metavariable U serves as a mnemonic for holes left unfilled by a hole-filling F. (In the simpler presentation of §2, only example constraints were generated, and each was annotated with a hole name.)

To define what it means for a filling F to constitute a valid solution for a set of constraints $K = (U; F_0)$, Figure 5 defines constraint satisfaction $F \models K$ by checking that (i) F subsumes any fillings F_0 in K and (ii) F satisfies the examples X_i for each hole $??_{h_i}$ constrained by K.

When analyzing multiple subexpressions, several unevaluation rules—discussed below—generate multiple sets of constraints that must be combined. Figure 6 shows the signature of two constraint

Unevaluation Constraint Merging (in § A.5)

Fig. 6. Live Bidirectional Example Checking via Live Unevaluation.

Proc. ACM Program. Lang., Vol. 4, No. ICFP, Article 109. Publication date: August 2020.

merge operators. The "syntactic" merge operation $K_1 \oplus K_2$ pairwise combines example contexts U and fillings F in a straightforward way. Syntactically merged constraints may describe holes $??_h$ both with example constraints X in U and fillings in F; the "semantic" operation Merge(K) uses live bidirectional example checking to check consistency in such situations. The full definitions can be found in the appendix (§ A.5).

Simple Unevaluation Rules. Analogous to the five example satisfaction rules (prefixed "XS-" in Figure 5) are the U-Top rule to unevaluate any result with \top and the U-Unit, U-Pair, U-Ctor, and U-Fix rules to unevaluate determinate results. The base case in which unevaluation generates example constraints is for hole closures [E]?? $_h$ —the U-Hole rule generates the (named) example constraint $h \mapsto (E \vdash \bullet \models ex)$.

The U-Fix rule refers to bidirectional example checking—evaluation followed by unevaluation—to "test" that a function is consistent with an input-output example. For instance, to unevaluate the function closure [zero \mapsto 0] λx .?? $_h$ with $\{1 \to 2\}$, first, the function application is evaluated: the closure environment is extended to bind the input example $x \mapsto \lfloor 1 \rfloor$, and the function body is evaluated to result [zero \mapsto 0, $x \mapsto \lfloor 1 \rfloor$]?? $_h$. Second, the output example 2 is unevaluated to this result, for which U-Hole generates the constraint $h \mapsto (\text{zero} \mapsto 0, x \mapsto \lfloor 1 \rfloor \vdash \bullet \models 2)$. (Valid fillings for ?? $_h$ include S (S Z), S x, and S (S zero).)

The remaining rules, discussed below, transform "indirect" unevaluation goals for more complex indeterminate results into "direct" examples on holes.

Indeterminate Function Applications. Consider an indeterminate function application r_1 r_2 , with the goal to satisfy ex. For results r_2 that are simple (first-order) values v_2 , the U-APP rule unevaluates the indeterminate function r_1 with the input-output example $\{v_2 \rightarrow ex\}$.

In general, the argument r_2 may include holes that would later appear in elimination position when r_1 is filled and the application resumes. For results r_2 that are not simple values, it is not possible to generate sufficient constraints locally to ensure that r_1 r_2 satisfies ex. For instance, if r_2 is of the form [E]??h, the hypothetical constraint " $\{([E]$?? $h) \rightarrow ex\}$ " would not provide any information about which input values the function r_1 must map to results that satisfy ex. As such, there is no unevaluation rule for arbitrary indeterminate application forms.

Indeterminate Projections. The U-PRJ-1 and U-PRJ-2 rules use \top for the component to be left unconstrained. For example, unevaluating $\text{prj}_1[E]$?? $_h$ with 1 generates $h \mapsto (E \vdash \bullet \models (1, \top))$.

Indeterminate Case Expressions. Recall from §2.3 the goal to unevaluate an indeterminate case expression with the number 1: case [-]?? $_h$ of $\{Nothing \to \emptyset; Just x \to x\} \Leftarrow 1$. Intuitively, this should require $h \mapsto (-\vdash \bullet \models Just 1)$.

To compute this constraint, the U-Case rule considers each branch j. The first premise unevaluates the scrutinee r with $C_j op$ to the scrutinee r, generating constraints K_1 required for r to produce an application of constructor C_j . If successful, the next step is to evaluate the corresponding branch expression e_j and check that it is consistent with the goal ex. However, the argument to the constructor will only be available after all constraints are solved and evaluation resumes.

We introduce the *inverse constructor application* C_j^{-1} r (Figure 3) to bridge this gap between constraint generation and constraint solving. To proceed down the branch expression, we bind the pattern variable x_j to C_j^{-1} r. Locally, this allows the third premise of U-Case to check whether the branch expression e_j satisfies ex. For the example above, the result of evaluating the second branch expression, x, is Just $^{-1}$ ([-]?? $_h$). Unevaluating Just $^{-1}$ ([-]?? $_h$) with 1 generates the constraint $h \mapsto (-\vdash \bullet \models Just ^{-1})$. Finally, the U-INVERSE-CTOR rule transfers the example from the inverse constructor application to a constructor application, producing $h \mapsto (-\vdash \bullet \models Just ^{-1})$.

Indeterminate Case Expressions: Guessing Scrutinees. The interplay between U-CASE and U-INVERSE-CTOR allows unevaluation to resolve branching decisions by generating constraints without the obligation to synthesize expressions that satisfy them. A downside of this "lazy" approach is the significant degree of non-determinism; indeed, many of the generated sets of constraints may be unsatisfiable.

As a more efficient approach in situations where the full expressiveness of U-Case is not needed, the U-Case-Guess rule "eagerly" resolves the direction of the branch by guessing a hole-filling F' via a non-deterministic uninterpreted function $Guesses(\Delta, \Sigma, r)$, and checking whether this filling resumes the scrutinee r to an application of a constructor C_j , where C_j is one of the n data constructors for the datatype D of the scrutinee. If so, the direction of the branch has been determined, so the last step is to unevaluate the jth branch expression e_j with the goal example ex, in an appropriately extended environment.

For instance, consider again the goal case [E]?? $_h$ of $\{\text{Nothing} \to \emptyset$; $\text{Just } x \to x\} \Leftarrow 1$ but here with the environment $E = \text{nothing} \mapsto \text{Nothing}$, $\text{just} \emptyset \mapsto \text{Just} \emptyset$, $\text{just} 1 \mapsto \text{Just} 1$. The Guesses function might choose the filling $F' = h \mapsto \text{just} 1$, which resumes the scrutinee [E]?? $_h$ to $\text{Just} \ 1$. In the environment extended with $x \mapsto 1$, the corresponding branch expression x evaluates to the result 1. Unevaluating this result with the example 1 succeeds via U-Ctor and U-Unit without generating additional constraints. (If guessing fills ?? $_h$ with nothing or just \emptyset , the result, \emptyset , of the branch expression would fail to unevaluate to 1.)

Whereas the U-Hole rule is the source of example constraints U produced by unevaluation, the U-Case-Guess rule is the source of hole-filling constraints F. We describe our concrete implementation of *Guesses* in §5.

4 SYNTHESIS PIPELINE

Live bidirectional evaluation addresses the challenge of checking example satisfaction for programs with holes. In this section, we define a synthesis pipeline that uses live bidirectional evaluation to (1) derive example constraints from asserts and (2) solve the resulting constraints.

Constraint Collection (§ 4.1) Constraint Solving (§ 4.2)
$$p \Rightarrow r; A \quad Simplify(A) \triangleright K \quad Solve(K) \rightsquigarrow F$$

Overview Program: Plus. Before describing each of these components formally, we summarize how they will fit together to synthesize the plus function in §2.1:

```
let plus = ??_0 in assert ([plus 0 1, plus 2 0, plus 1 2] == [1, 2, 3])
```

First, when evaluating the program, the left-hand side of the assert produces three nested, indeterminate function calls: $[([-]??_0 \ 0)\ 1,\ ([-]??_0\ 2)\ 0,\ ([-]??_0\ 1)\ 2]$. Structurally comparing this list of indeterminate results with the list of values $[1,\ 2,\ 3]$ yields three *assertion* predicates A as a side-effect (via rules EVAL-AND-ASSERT, RC-CTOR, and RC-ASSERT-1, discussed below):

$$A = (([-]??_0 \ 0) \ 1) \Rightarrow 1, (([-]??_0 \ 2) \ 0) \Rightarrow 2, (([-]??_0 \ 1) \ 2) \Rightarrow 3$$

Second, we use live bidirectional example checking (Live-Check) to convert—i.e. Simplify—the assertions A into example constraints U (via U-App and U-Hole):

$$U = 0 \mapsto ((-\vdash \bullet \models \{0 \rightarrow \{1 \rightarrow 1\}\}), (-\vdash \bullet \models \{2 \rightarrow \{0 \rightarrow 2\}\}), (-\vdash \bullet \models \{1 \rightarrow \{2 \rightarrow 3\}\}))$$

The simplified constraints K = (U; -) contain an empty hole-filling because U-Case-Guess is not invoked to resolve any indeterminate case expressions.

Finally, the holes in U are solved one at a time; here there is only $??_0$. Solving one hole may generate new subgoals (Refine and Branch) or new constraints on existing goals (Guess-And-Check).

The search path sketched in § 2.1 produces the solution F below that solves the constraints K = (U; -). Each step is annotated with the rules used to conclude the subderivation.

```
\begin{array}{lll} 0 & \longmapsto & \text{fix } f_1 \ (\lambda \text{m.fix } f_2 \ (\lambda \text{n.??}_1)) & \text{Solve-One, Refine, Refine-Fix (twice)} \\ 1 & \longmapsto & \text{case m} \ \{\text{Z} \rightarrow ??_2 \ ; \text{S m'} \rightarrow ??_3\} \\ 3 & \mapsto & \text{S } ??_4 & \text{Solve-One, Refine, Refine-Ctor} \\ 4 & \mapsto & \text{plus m'} \ n & \text{Solve-One, Guess-and-Check, Live-Check} \\ 2 & \mapsto & n & \text{Solve-One, Guess-and-Check, Live-Check} \end{array}
```

4.1 Constraint Collection

Figure 7 defines a *program* to be an expression followed by an assert $(e_1 = e_2)$ statement. Changes to allow asserts in arbitrary expressions are discussed in §7.

Assertions via Result Consistency. A typical semantics for assert would require the expression results r_1 and r_2 to be equal, otherwise raising an exception. Instead, rather than equality, the Eval-and-assert rule in Figure 7 checks result consistency, $r_1 \equiv_A r_2$, a notion of equality modulo assumptions A about indeterminate results. Determinate results are consistent if structurally equal, as checked by the RC-Refl, RC-Pair, and RC-Ctor rules. Indeterminate results r are consistent with simple values v—the RC-assert-1 and RC-assert-2 rules generate assertion predicates $r \Rightarrow v$ in such cases. Figure 7 also defines assertion satisfaction $F \models A$: for each assertion $r_i \Rightarrow v_i$ in A, the indeterminate result r_i should resume under filling F and produce the value v_i .

Assertion Simplification. For each assertion $r_i \Rightarrow v_i$, the Simplify procedure in Figure 7 converts the simple value into an example $\lfloor v_i \rfloor$ and unevaluates it to r_i to generate example constraints.

THEOREM (SOUNDNESS OF ASSERTION SIMPLIFICATION).

If $Simplify(A) \triangleright K$ and $F \models K$, then $F \models A$.

Program Evaluation

 $p \Rightarrow r; A$

$$\begin{array}{lll} \underline{\mathbf{Programs}} & p & ::= & \mathrm{let\,main} = e \; \mathrm{in\,assert} \; (e_1 = e_2) \\ \underline{\mathbf{Assertions}} & A & ::= & \left\{ \begin{array}{l} r_i \Rightarrow v_i \end{array} \right\}^{i \in [n]} \\ \\ \underline{- \vdash e \Rightarrow r} & \left\{ \begin{array}{ll} \mathrm{main} \mapsto r \vdash e_i \Rightarrow r_i \end{array} \right\}^{i \in [2]} & \underline{r_1 \equiv_A r_2} \\ \\ \mathrm{let\,main} = e \; \mathrm{in\,assert} \; (e_1 = e_2) \Rightarrow r \; ; A \end{array}$$

Result Consistency

Fig. 7. Constraint Collection.

4.2 Constraint Solving

The constraints K, of the form $(U; F_0)$, include filled holes F_0 from constraint simplification (cf. U-Case-Guess) and a set U of unfilled holes constrained by examples. Figure 8 and Figure 9 define an algorithm to synthesize expressions for unfilled holes, generalizing MYTH to use live bidirectional evaluation and to fill interdependent holes.

The Solve(U; F) procedure in Figure 8 is the entry point for filling the holes in U. The Solve-Done rule handles the terminal case, when no unfilled holes remain. Otherwise, the Solve-One rule chooses an unfilled hole $??_h$ and forms the synthesis goal $(\Gamma \vdash \bullet_h : T \models X)$ from the hole type and example contexts Δ and U. The *hole synthesis* procedure—discussed next—completes the task, which, in Smyth, may assume constraints K over other holes. Any such constraints K are combined with the existing ones using the semantic Merge operation (cf. §3.5), and the resulting constraints K' are recursively solved.

Hole Synthesis. For each unfilled hole, the hole synthesis procedure F; $(\Gamma \vdash \bullet_h : T \models X) \leadsto_{\text{fill}} K$; Δ' augments guessing-and-checking (Guess-And-Check) with example-directed refinement (Refine) and branching (Branch); these rules are discussed in turn below.

The structure of hole synthesis in Core Smyth closely follows Myth [Osera and Zdancewic 2015], which presents a novel approach to synthesis by analogy to proof search for *bidirectional type checking* [Pierce and Turner 2000]. We refer the reader to their paper for a comprehensive account of their ideas; we limit our discussion to the most important technical differences.

Fig. 8. Constraint Solving with Guessing, Refinement, and Branching. We at once define Refine and Branch by differentiating the two by color; the signature of the branching judgement extends that of the refinement judgement with an additional input F and an additional output K.

Proc. ACM Program. Lang., Vol. 4, No. ICFP, Article 109. Publication date: August 2020.

Besides modifications to notation and organization, the primary differences of our formulation are that hole synthesis: (i) refers to the filling F from previous synthesis tasks completed by Solve; (ii) may generate example constraints over other holes in the program; (iii) may fill other holes in the program besides the goal $??_h$; and (iv) includes a rule, Defer, to "fill" the hole with $??_h$ when all examples are top—these constraints are not imposed directly from program assertions, but are created internally by unevaluation.

 $(\Gamma \vdash \bullet : T_1 \rightarrow T_2 \models X) \rightsquigarrow_{\text{refine }} e \dashv G_1$

Fig. 9. Guessing, Refinement, and Branching.

Guessing-and-Checking. The Guess-And-Check rule uses the procedure $(\Gamma \vdash \bullet : T) \rightsquigarrow_{\text{guess}} e$ in Figure 9 to *guess* a well-typed expression without holes. Guessing amounts to straightforward inversion of expression type checking rules; the appendix (§A.6) provides the full definition.

The candidate expression e is checked for consistency against the examples X using live bidirectional example checking (cf. §3.5 and Figure 6). Whereas example checking in MYTH produces a Boolean outcome, example checking in Core Smyth may assume constraints K over other holes. The constraints that arise from (live bidirectional) example checking are the source of the aforementioned differences (i), (ii), and (iii) compared to the MYTH hole synthesis procedure.

Refinement. The Refine rule refers to the *refinement* procedure $(\Gamma \vdash \bullet : T \models X) \leadsto_{\text{refine}} e \dashv G$ in Figure 9 to quickly synthesize a partial solution e which refers to freshly created holes $??_{h_1}$ through $??_{h_n}$ described by subgoals G. Using these results, Refine generates output constraints comprising the partial solution $h \mapsto e$ and the new unfilled holes $h_1 \mapsto X_1$ through $h_n \mapsto X_n$. For the purposes of metatheory, the typings for fresh holes are recorded in the hole type context Δ' .

Each refinement rule first uses Filter(X) to remove top examples and then inspects the structure of the remaining examples. For unit-type goals, Refine-Unit simply synthesizes the unit expression (). For pair-type goals, Refine-Pair synthesizes the partial solution $(??_{h_1}, ??_{h_2})$, creating two subgoals from the type and examples of each component. The Refine-Ctor rule for datatype goals D works similarly when all of the examples share the same constructor C.

The refinement rules described so far are essentially the same as proposed by Osera and Zdancewic [2015]. But rather than explicitly naming subgoals G and "sending" them to a top-level Solve procedure, the refinement rules in Myth recursively call hole synthesis to solve subgoals immediately. In Core Smyth, we separate the creation of subgoals from solving in order to facilitate the "global" reasoning necessary to synthesize recursive function literals without trace-complete examples, discussed next.

For function-type goals, the Refine-Fix rule synthesizes the function sketch fix $f(\lambda x.??_{h_1})$. The environments inside example constraints X_1 for the function body $??_{h_1}$ bind f to this function sketch (closed by the appropriate environments E_i). As a result, any recursive calls to f will evaluate to closures of $??_{h_1}$ (to be constrained by live bidirectional example checking), thus avoiding the need for trace-complete examples.¹

Branching. Lastly, the Branch rule refers to the procedure F; $(\Gamma \vdash \bullet : T \models X) \leadsto_{\text{branch}} e \dashv G$; K in Figure 9 to guess an expression on which to *branch*. (As mentioned, the signature of the branching procedure extends refinement with the additional input F and additional output K.)

The single rule, Branch-Case, chooses an arbitrary expression e (of arbitrary datatype D) to scrutinize, synthesizing the sketch case e of $\{C_i \ x_i \to ??_{h_i}\}^{i \in [n]}$ with subgoals h_i for each of the the constructors C_1 through C_n for the datatype D. The main task is to *distribute* the examples X onto appropriate subgoals. To determine which subgoal should be responsible for the jth example, the guessed scrutinee e is evaluated under the example constraint environment E_j to a result r_j .

Consider the particular scenario in which r_j has determinate form C_i r'_j , for some constructor C_i . The C_i branch will surely be taken under environment E_j , so the constraint $(E_j, x_i \mapsto r'_j \vdash \bullet \models ex_j)$ is added to the examples X_i for the subgoal of that branch. If r_j is *indeterminate*, however, we cannot be sure "which way" the scrutinee will evaluate and thus which branch to "assign" the subgoal.

¹ For the constraint environments in $K_{4,1}$ and $K_{4,2}$ in § 2.1, the refinement rule for recursive functions in MYTH would bind plus to trace-complete examples {0 1 \rightarrow 1, 2 0 \rightarrow 2, 1 2 \rightarrow 3, . . . }. In addition to usability obstacles of trace-completeness, their theory is complicated by a non-standard *value compatibility* notion [Osera and Zdancewic 2015, §3.3] to approximate value equality because input-output examples serve as a "lookup table" to resolve recursive calls.

Therefore, in general, Branch-Case non-deterministically chooses a branch $\alpha_j \in [n]$ for each example j and relies on unevaluation to determine whether r_j can satisfy $C_{\alpha_j} \top$ (assuming some constraints K_j). The constructor simplification operation $[\![r]\!] = (\text{if } r = C_i^{-1} (C_i r') \text{ then } r' \text{ else } r)$ helps streamline the determinate and indeterminate scenarios in the definition of Branch-Case. This flexibility—analogous to U-Case (cf. Figure 6)—is needed to synthesize several inside-out recursive functions (without trace-complete examples), as described in the next section.

THEOREM (SOUNDNESS OF SYNTHESIS).

```
If \Sigma; \Delta \vdash p : T and p \Rightarrow r; A and Simplify(A) \triangleright K and \Sigma; \Delta; Solve(K) \leadsto F; \Delta', then \Sigma \vdash F : \Delta' and F \models A.
```

5 IMPLEMENTATION

We implemented SMYTH (https://github.com/UChicago-PL/smyth) in approximately 6,500 lines of OCaml code, not including the front-end to SMYTH nor the experimental setup. Compared to the core language in Figure 3, our implementation supports Haskell/Elm-like syntax, *n*-ary tuples, let-bindings, let-bound recursive function definitions, and user-defined datatypes. Our implementation also supports higher-order function examples (used in the experiments below) and polymorphism (not used below, but described in Appendix C) following Osera and Zdancewic [2015] and Osera [2015], respectively; these features are orthogonal to our contributions.

Our prototype lacks many of the syntactic conveniences used in code listings in §1 and §2 such as nested pattern matching, infix list operators (::) and (++), and type inference for holes. Following MYTH, we synthesize only structurally decreasing recursive functions, and we further require that the first argument to a recursive call be structurally decreasing. These are not fundamental challenges, but they result in slightly different code than shown in the paper.

Optimizations. We adopt two primary optimizations from MYTH. The first is to guess and cache only *proof relevant* [Anderson et al. 1992] elimination forms—variables x or calls f $e_1 \cdots e_n$ to variable-bound functions. The second is a *staging* approach to incrementally increase the maximum branching depth, the size of terms to guess as scrutinees, and the size of terms to guess in other goal positions. We generally adopt the same parameters used by Osera [2015], but with additional intermediate stages to favor small solutions. Furthermore, our parameters are "sketch-sensitive": case expressions in the sketch, if any, count against the branching depth budget.

To rein in the non-determinism of case unevaluation, our implementation is configured, first, to guess only variables and projections for the $Guesses(\Delta, \Sigma, r)$ procedure in the "eager" U-Case-Guess rule and, second, to bound the number of nested uses of the "lazy" U-Case rule.

6 EXPERIMENTS

We consider several questions regarding how our techniques—which address Limitations A and B of prior evaluator-based synthesis (§1)—translate into practical gains for users of synthesis tools.

- Compared to prior evaluator-based synthesizers, does SMYTH reduce the number of examples required to synthesize top-level, single-hole tasks?
- Unlike prior evaluator-based synthesizers, does Smyth support sketching tasks? Is the total specification burden less than when using examples alone?
- Can state-of-the-art logic-based synthesizers complete all tasks that SMYTH can?

To shed light on these questions, we designed four experiments based on the benchmarks used to evaluate MYTH. Expert examples are the de facto method for evaluating the *raw expressiveness* of synthesis techniques (e.g. [Albarghouthi et al. 2013; Feser et al. 2015; Frankle et al. 2016; Osera and Zdancewic 2015]). A notable exception is how Feser et al. [2015] evaluate the *robustness* of λ^2 using

randomly-generated examples as a "'lower bound' on a human user … who has no prior exposure to program synthesis tools." Inspired by these approaches, our experiments consider both "expert" and "random" users to investigate SMYTH's expressiveness and robustness.

We ran each of the SMYTH experiments on a Mid 2012 MacBook Pro with a 2.5 GHz Intel Core i5 CPU and 16 GB of RAM. We describe each experimental setup and summarize the results (Figure 10) in turn, followed by a discussion including limitations.

6.1 Experiment 1: No Sketches + Trace-Complete Examples

As a baseline experiment, we first run SMYTH on each MYTH benchmark—a top-level, single-hole task specified with the "full" set of trace-complete expert examples reported by Osera [2015]. Figure 10 (column 1) indicates that SMYTH passes 38 of the same 43 benchmarks (without sketches) in a similar amount of time (cf. [Osera 2015]).

Of the five MYTH benchmarks that failed in Experiment 1, SMYTH produced an over-specialized solution for one (list_even_parity) and did not terminate within 120 seconds for the remaining four (list_compress, tree_binsert, tree_nodes_at_level, and tree_postorder). The over-specialized term SMYTH synthesized for list_even_parity was smaller (AST size 14) than the desired term (size 16), which was correctly synthesized by MYTH. (SMYTH synthesizes and ranks the desired term second.) It is unclear why MYTH did not find and return the smaller solution, which is consistent with the examples provided; nevertheless, we classify this task as a failure. The four benchmarks for which SMYTH did not terminate are discussed further in §6.5.

Our validation process—which checks synthesized terms against a random set of examples from a reference implementation—revealed that the solution for list_filter reported by Osera [2015, p.171] is incorrect. As a workaround, we added one more (trace-complete) example to the reported set of 8 examples and observed that SMYTH synthesized a correct solution. We treat these 9 examples (marked with an asterisk in Figure 10) as the set of MYTH expert examples for this task.

6.2 Experiment 2: No Sketches + Non-Trace-Complete Examples

Second, we measured how many examples—both expert and random—Smyth requires to synthesize the Myth tasks when not limited to the trace-complete examples from Experiment 1.

Experiment 2a: No Sketches + Expert Examples. To construct expert examples for SMYTH on each of the 38 benchmarks it can synthesize, we manually removed sets of examples from the full test suite until SMYTH no longer synthesized a correct solution, i.e. a solution that conforms to a reference implementation of the desired solution. As such, there are no corresponding tasks for the five benchmarks that failed Experiment 1, as indicated by "•1" in Figure 10.

Of the 38 benchmarks, Figure 10 (column 2a) shows that SMYTH required fewer examples to synthesize all but four benchmarks (bool_neg, bool_xor, list_length, and nat_max), requiring on average 61% of the number of expert examples required by MYTH, with similar running times as in the baseline configuration (timing data not shown). To account for the 5 missing benchmarks, if we were to assume that SMYTH were extended with the MYTH-style trace-complete approach to synthesizing recursive functions as a backup synthesis procedure and that the remaining benchmarks would require all of the expert examples, then SMYTH would require on average 66% of the number of examples for the entire benchmark suite.

Experiment 2b: No Sketches + Random Examples. To evaluate the robustness of MYTH, we implemented a random example generator. For simplicity, our random generator does not support function types; therefore, we did not consider the 4 higher-order function benchmarks (list_filter, list_fold, list_map, and tree_map; these are marked "•2" in Figure 10). We also did not consider the four benchmarks that timed out in Experiment 1.

Fig. 10. Experiments.

Top-1(-R): 1st (recursive) solution valid. Time: Average of 10 runs, in seconds. 2a Average: 61% for 38 non-blank rows. (*Upper bound: 66% for all 43 rows.)

3a Average: 46% for 25 non-blank, non-error rows.

For each of the remaining 35 tasks, we generated N=50 sets of k random input examples (where k ranges from 1 to a reasonable upper bound depending on the benchmark) and used a task reference implementation to compute the corresponding outputs, thus producing N sets of input-output example sets of size k for each k. We fixed relatively small upper bounds on the AST sizes of the input examples generated to ensure the examples could reasonably be provided by a human, and,

rather than sampling inputs uniformly at random—in which case, e.g., a list of length 3 would be twice as likely as a list of length 2—we first sampled different *shapes* for the data structures (Lists and Trees) uniformly at random, then filled in base values at the AST leaves uniformly at random. Furthermore, we required that each set of examples (regardless of size) contains the unique "minimal input" to the function, that is, the input that consists of the minimal value for each type of each argument of the function, where, for Nats, the minimal value is 0, for Lists, it is the empty list, and for Trees, it is a leaf.

Entries in Figure 10 (column 2b) show two values: the minimum k for which SMYTH synthesized the desired solution within a t=1 second timeout for 50% of the N sets of examples, and the minimum such k to achieve 90% success; the appendix (Appendix B) includes graphs for each benchmark. Several entries require explanation. Two benchmarks are marked with a superscript "t=3" (tree_collect_leaves and tree_preorder) and one benchmark is marked with a superscript "t=10" (tree_count_nodes) to indicate they they required a longer time-out. For tree_count_nodes, we do not report the minimum k value for 90% (marked " \downarrow "), because the percentage dips below for subsequent values of k. One benchmark is marked "(-,-)" (list_even_parity) and did not achieve a 50% success for reasonably-small values of k. For this benchmark, we hypothesize that our simply-typed approach cannot glean enough information from its input type, BooleanList.

To analyze these k-values, we consider the difference $k_p' := k_p - k_{\text{expert}}$ for each benchmark that was successfully synthesized in this experiment, where p is the required success rate

	median k_p'	$\max k'_p$
p = 50%	0	2
p = 90%	1	9

(either 50% or 90%) and $k_{\rm expert}$ is the number of SMYTH expert examples for Experiment 2a. The value k_p' thus represents how many more examples are needed, compared to the expert set, to achieve success p% of the time. The adjacent table summarizes the distribution of k_p' for Experiment 2b; additional statistics and corresponding histograms can be found in the appendix (Appendix B).

6.3 Experiment 3: Base Case Sketching Strategy

Experiments 1 and 2 considered tasks without sketches from the user. As a third experiment, we systematically converted the MYTH benchmarks into a suite of small sketching tasks by employing a simple *base case sketch strategy*—performing case analysis on the correct argument of the function, filling in the base case properly, and leaving a hole in the recursive branch. Of the 38 tasks, 27 are recursive and thus subject to this strategy. The remaining, non-recursive tasks are marked "•3".

In Figure 10 and the following, we write 1 + n to denote a specification with n examples in addition to the base case sketch; our accounting treats the specification burden of the base case sketching strategy as equivalent to 1 example. (We could report AST sizes of sketches and examples, but even these would be just a rough proxy for the "complexity" of a specification.)

Experiment 3a: Base Case Sketches + Expert Examples. Analogous to Experiment 2a, we manually removed sets of examples from the full trace-complete expert examples until SMYTH no longer successfully completed the task. For this experiment, however, because the base case strategy pertains to recursive functions, we considered a task successful if the smallest *recursive* solution was correct, rather than simply the smallest solution overall. Figure 10 (column 3a) shows the results of this experiment.

For 25 of these 27 tasks that succeeded, SMYTH on average required smaller total specifications with base case sketches than with no sketches. On average, specifications were 46% the size of the full trace-complete examples—compared to 57% without a sketch (average, not shown, of 25 rows in the Experiment 2a column). Given the sketches, the average number of examples required was 2.12; list_sorted_insert required 7, while the rest required between 1 and 4.

Three tasks that succeeded (list_filter, list_pairwise_swap, and list_sorted_insert) required sketch-sensitive staging parameters (§ 5). This is because Smyth's staging parameters increase branching depth before scrutinee size, and a relatively large scrutinee is needed for the desired solution; compared to when no sketch is provided, sketch-insensitive staging parameters effectively "penalize" the sketch for having introduced a case. Before we accounted for branching depth in the user-provided sketch, Smyth synthesized overspecialized solutions for these three tasks even with the full set of Myth expert examples.

Two of the 27 tasks failed this experiment. For list_even_parity, Smyth synthesized an over-specialized solution (even with sketch-sensitive staging parameters). For list_concat, Smyth actually synthesized "list_rev_concat," which appends together a list of lists in *reverse* order. The Myth expert examples are not sufficient to distinguish these two functions; Smyth returns both, but they have the same AST size and the desired solution is arbitrarily ranked second.

Experiment 3b: Base Case Sketches + Random Examples.

Analogous to Experiment 2b, we generated random input-output examples for the benchmarks, this time in addition to providing

	median k_p'	$\max k_p'$
p = 50%	2	6
p = 90%	4	14

the base case sketches. We again consider the difference $k_p' := k_p - k_{\rm expert}$ for each benchmark that was successfully synthesized in this experiment, where $k_{\rm expert}$ is now the number of SMYTH expert examples for Experiment 3a rather than for Experiment 2a. The adjacent table summarizes the distribution of k_p' for Experiment 3b; additional data can be found in the appendix (Appendix B).

6.4 Experiment 4: Programming-by-Example in Leon and Synquid

The previous experiments evaluate the improvements in SMYTH compared to prior evaluator-based techniques. In our final experiment, we run several of our "programming-by-example" tasks on Leon and Synquid. The goal is to understand whether—from the perspective of a user who wishes to specify tasks through examples—Leon or Synquid are strictly more powerful than SMYTH. That is, can Leon or Synquid solve every task that SMYTH can?

We systematically generated Scala and Haskell versions of our benchmarks to test Leon and Synquid, respectively. Because this experiment is designed to answer a very simple question, we did not develop a thorough experimental environment with random examples or multiple trials. Instead, we used web interfaces to Leon and Synquid to test benchmarks.²

First, we tested the small sketching tasks from §1 and §2. As described in §1, both tools fail to complete the stutter_n task. We also found that Synouid fails to complete the four sketching tasks from Figure 2 and that Leon successfully completes max and odd but fails on minus and mult.

We then tested the tools for the top-level, single-hole tasks used in Experiments 1 and 2a with trace-complete and non-trace-complete expert examples, respectively. Besides the function to synthesize, we used simple types (without examples or precise logical predicates) for all functions in the context. Four benchmarks had the same number of expert examples in Experiment 2a as they did in Experiment 1 and thus do not have corresponding tasks in Experiment 4 (marked "o-4").

Figure 10 (columns 4) show the results. Leon and Synquid successfully completed many tasks (marked \checkmark), but failed several tasks for a variety of reasons: terminating without producing solutions or not terminating within a timeout (X^0); returning over-specialized solutions (X^1); and not being able to directly express higher-order function examples (X^2). As expected, Synquid failed to synthesize recursive functions without inductive (i.e. trace-complete) specifications (column 4, 2a).

 $^{^2\} https://leon.epfl.ch/\ and\ http://comcom.csail.mit.edu/comcom/\#Synquid.\ Accessed\ February\ 2020\ and\ May\ 2020.$

³ Earlier results from this experiment revealed an implementation issue in Synquid involving the axiomatization of recursive datatypes in the underlying logic. This issue—which prevented the desired solutions for many benchmarks from typechecking, even when given trace-complete examples—has since been fixed [Polikarpova 2020].

These results are not entirely surprising, as the underlying techniques are not necessarily tailored to the structure of examples encoded as conjunctions-of-implications. This suggests opportunities for further improvements to both evaluator- and logic-based techniques, for instance, by integrating live bidirectional evaluation into more fine-grained logic-based techniques.

As a final note, this experiment was *not* intended to evaluate whether SMYTH is "better" than the logic-based tools. Indeed, many tasks involving complex invariants are beyond the reach of evaluator-based techniques, SMYTH included. Polikarpova et al. [2016, §4.3] provide some empirical comparison between example-based and logic-based specifications on several common benchmarks.

6.5 Limitations and Discussion

Failing Benchmarks. One major optimization in MYTH that we have not implemented is to cache solutions F—which correspond to MYTH's "refinement trees"—across branches of the search. This optimization does not directly carry over to our setting because, unlike in MYTH, synthesized terms in SMYTH may introduce different, conflicting assumptions across different branches of search. Thus, our first hypothesis is that suitably extending caching to our setting could help synthesize the remaining tasks (although the difficulty of this task is unclear).

Of the five benchmarks not successfully synthesized in our implementation, MYTH finds four solutions with *inside-out recursion* [Osera 2015], which pattern match on a recursive call to the function being synthesized. Inside-out solutions are smaller than more "natural" ones, and sometimes they are the only solutions to tasks in MYTH and SMYTH because only elimination forms are enumerated and let-bindings are not synthesized [Osera 2015]. Although SMYTH does synthesize an inside-out solution for one benchmark (list_pairwise_swap), inside-out recursion relies heavily on the non-determinism of Branch-Case and U-Case. Accordingly, our second hypothesis is that additional tuning for these sources of non-determinism could help synthesize the necessary inside-out recursion.

Scalability. Each benchmark in our experiments included the minimal context—as defined in the MYTH benchmarks—required to synthesize the desired solution. In addition to minimal contexts, the MYTH paper also reported results in the presence of a slightly larger context and ran into scalability issues on some benchmarks. Though we did not run these versions of the benchmarks, we inherit any scalability issues of the prior techniques.

Moreover, our approach introduces new sources of non-determinism. To scale to much larger programs with complex control flow, static reasoning (interleaved with concrete evaluation) could be used to prune unsatisfiable or heuristically "difficult" sets of example constraints. Orthogonal techniques for scaling to large contexts with additional components [Feng et al. 2017b; Guo et al. 2020; Gvero et al. 2013] might also be incorporated into our approach in future work.

Assertions. Our formulation and thus our benchmarks support only top-level asserts. To allow asserts in arbitrary expressions (as needed for larger and more realistic sketching tasks), evaluation and resumption could be extended to generate assertions A as a side-effect, to be translated by Simplify into constraints for synthesis. We expect the algorithmic changes to be straightforward, but the extended definition of assertion satisfaction along with the corresponding correctness properties and proofs are more delicate; we leave this task for future work.

Polymorphism. Of the 38 tasks that SMYTH successfully synthesized in Experiment 1, 23 can be specified with a polymorphic type signature rather than a monomorphic one. We re-ran Experiments 2 and 3 with polymorphic type signatures, which are supported in our implementation but are not included in our formal development. As described in the appendix (Appendix C), polymorphic type signatures lead to a modest reduction in the number of examples needed for synthesis.

7 RELATED WORK

Our work generalizes the theory of evaluator-based synthesis techniques to (a) eliminate the need for trace-complete examples and (b) to support sketching—addressing Limitations A and B from §1. We build directly on the work of Osera and Zdancewic [2015], so we discussed MYTH throughout the paper. To conclude, we discuss several additional directions of related work.

7.1 Live Evaluation and Bidirectional Evaluation

The key technical mechanism underlying our approach is live bidirectional evaluation, the combination of live evaluation and live unevaluation. We choose the term "live" to describe partial evaluation of sketches, following terminology of Omar et al. [2019]. Future work must address important usability and scalability questions to further develop and deploy our techniques in interactive, *live programming* environments [Kubelka et al. 2018; Tanimoto 2013].

Live Evaluation (HAZELNUT LIVE). We adapt the technique for partially evaluating sketches from HAZELNUT LIVE [Omar et al. 2019]. In contrast to solver-based and symbolic execution techniques for partially evaluating programs with holes (e.g. [Bornholt and Torlak 2018; Feng et al. 2017a; Wang et al. 2020]), live evaluation is a form of concrete evaluation, adapting ideas from contextual modal type theory [Nanevski et al. 2008]. Omar et al. [2019, §5] detail the relationship to related work on partial evaluation. HAZELNUT LIVE does not offer any form of synthesis; their "fill-and-resume" feature refers to ordinary program edits by the user.

We note some technical differences in our formulation. We choose a natural semantics presentation [Kahn 1987] for Core Smyth rather than one based on substitution. Whereas their fill-and-resume mechanism is defined using contextual substitution, our formulation instead defines evaluation resumption. Hazelnut Live also includes hole types to support gradual typing [Siek and Taha 2006; Siek et al. 2015], a language feature orthogonal to the (expression) synthesis motivations for our work. Finally, Omar et al. [2019] present a bidirectional type system [Chlipala et al. 2005; Pierce and Turner 2000] that, given type-annotated functions, computes hole environments Δ ; the same approach can be employed in our setting without complication.

Bidirectional Evaluation (Sketch-N-Sketch). Several proposals define unevaluators, or backward evaluators, that allow changes to the output value of an expression (without holes) to affect changes to the expression [Matsuda and Wang 2018; Mayer et al. 2018; Perera et al. 2012]. Though related by analogy and terminology, our novel live unevaluation mechanism shares essentially no technical overlap with the above techniques. The prior backward evaluators essentially only modify constant literals of base type—which can be thought of as "non-empty" holes that are subject to replacement—at the leaves of an existing program, whereas our live unevaluator propagates example constraints to holes of arbitrary type and in arbitrary position.

An environment-style semantics is purposely chosen for each of the above unevaluators, because value environments provide a sufficient mechanism for tracing value provenance during evaluation. In contrast, our unevaluator could just as easily be formulated with substitution; in either style, hole expressions are labeled with unique identifiers, which provide the necessary information to generate example constraints.

7.2 Program Synthesis

We conclude with a broader discussion of the evaluator- and logic-based synthesis techniques that we introduced in § 1. We use the term "functional programming"—in contrast to "domain-specific"—to describe languages in which users (and synthesizers) write unrestricted programs in a richly-typed functional language (i.e. with directly recursive functions on algebraic datatypes).

7.2.1 Evaluator-Based Synthesis Techniques. We chose this term in §1 to describe synthesis algorithms in which the core search strategy uses *concrete* evaluation to "check" candidate terms, typically against input-output example specifications.

Programming-by-Example (PBE) for Domain-Specific Languages. Programming-by-example techniques have been developed for numerous domain-specific applications, including string transformations [Gulwani 2011] (including bidirectional ones [Miltner et al. 2019]), shell scripting [Gulwani et al. 2015], web scraping [Chasins et al. 2018], parallel data processing [Smith and Albarghouthi 2016], and generating vector graphics [Hempel et al. 2019]. See Gulwani et al. [2017] for a recent survey of developments. These approaches generally synthesize entire programs. To allow experts to provide partial implementations, it should be possible to formulate notions of live bidirectional evaluation of these domain-specific techniques.

 λ^2 [Feser et al. 2015] synthesizes functions in a (first-order) functional programming language (with higher-order components). λ^2 enumerates open hypotheses (i.e. sketches) involving calls to a fixed set of primitive List and Tree combinators (e.g. filter and map), and relies on axioms for deductive reasoning to convert examples for a goal into examples for the subgoals. This process is akin to refinement in МҮТН, and also helps prune unsatisfiable example constraints (e.g. if a map hypothesis requires input and output lists of different lengths).

However, function examples are not used used to "refine" the search; their deduction rule for general recursion essentially falls back on raw term enumeration, and their checking routine operates only on *closed hypotheses* (without holes). In other words, examples need not be trace-complete because they are not used to help synthesize recursive function literals. Although the language supported by λ^2 nominally includes direct recursive function literals [Feser et al. 2015, §3], in practice, their implementation synthesizes solutions *only* by composing the primitive data structure combinators [Feser 2016, 2020], and furthermore does not introduce non-trivial matches on inductive data [Feser 2020]. λ^2 can synthesize a variety of functional programming tasks, similar to the Myth and Smyth benchmarks, including with randomly-generated examples (cf. §6) and with significantly larger contexts than used in the Myth and Smyth experiments. But because λ^2 does not search for directly recursive functions, it is fundamentally a more domain-specific technique than Myth and Smyth.

For the domain of table transformations, Morpheus extends the approach of λ^2 with (i) SMT-based reasoning to perform more powerful deduction and (ii) partial evaluation of sketches. Viser [Wang et al. 2020] further improves upon the techniques in Morpheus, by providing *backward* reasoning about program sketches using symbolic reasoning over logical and subset constraints. (Viser also integrates a domain-specific language for visualization, resulting in a visualization-by-example tool.) Sketches in both Morpheus and Viser are drawn from a first-order, domain-specific language of table transformations. In contrast, Smyth performs bidirectional reasoning about program sketches (a) in a *general-purpose* richly-typed functional programming language (as opposed to domain-specific table transformation languages), (b) using techniques based on concrete evaluation (rather than SMT solving and other symbolic reasoning techniques).

PBE for Functional Programming. Two prior evaluator-based systems synthesize recursive functions. Escher [Albarghouthi et al. 2013] does so for an untyped, first-order functional language (with base types rather than inductive datatypes), relying on run-time type errors to help rule out candidate terms. Myth [Osera and Zdancewic 2015] pioneered the idea to synthesize recursive functions over algebraic datatypes using search techniques inspired by bidirectional typing [Pierce and Turner 2000] and relevant proof search [Anderson et al. 1992; Byrnes 1999]. Both Escher and Мутh require trace-complete examples. As discussed next, the bidirectional typing approach of Мутh has influenced several logic-based approaches to synthesis.

7.2.2 Logic-Based Synthesis Techniques. We chose this term in §1 to describe synthesis algorithms that use *symbolic*, rather than concrete, evaluation to enumerate terms, and which operate on more fine-grained, precise logical specifications than examples.

PBE for Functional Programming via Refinement Types. Frankle et al. [2016] reformulate MYTH by recasting concrete examples in a type language of intersection and singleton types. Rather than employing concrete evaluation, they perform (symbolic) proof search within their rich type language. Their formal development includes union and negation types, which allows more than just examples (with concrete input and output values) to be specified. Their implementation further supports type polymorphism, with symbolic values as examples. The combination of negation and polymorphism admit what Polikarpova et al. [2016] dub "generalized examples," which facilitate smaller specifications for several MYTH benchmarks. (Generalized examples resemble the symbolic input-output examples supported by Leon for program repair [Kneuss et al. 2015].) This reformulation of (generalized) examples suffers the same Limitations A and B as Escher and MYTH. It would be valuable to extend SMYTH in future work with similar typing constructs.

Program Sketching. Sketch [Solar-Lezama 2008; Solar-Lezama 2009; Solar-Lezama et al. 2005, 2006] is an imperative, C-like language that pioneered the approach of program synthesis by sketching. Rosette [Torlak and Bodik 2013, 2014] further develops this approach within the untyped functional language Racket. Holes in Sketch and Rosette range only over integers and booleans, but these can be used to define richer types of expressions. The mechanisms for such syntax-guided synthesis [Alur et al. 2013] are particularly powerful in Rosette, which leverages the metaprogramming facilities in Racket. As Inala et al. [2017, §6] suggest, one could embed the syntax and semantics of a richly-typed, general-purpose functional programming language in Rosette. There is no obvious reason to expect recursive functions over user-defined algebraic datatypes embedded in this way to be readily synthesized, but this approach would be an interesting experiment.

Solver-Based Techniques for Functional Programming. Synouid [Polikarpova et al. 2016] and Leon [Kneuss et al. 2013] directly support sketching in richly-typed functional languages using solver-based techniques driven by logical specifications. Synouid employs bidirectional typing (like Myth) in a setting with SMT-based refinement types [Rondon et al. 2008; Vazou et al. 2013]. Synouid furthermore introduces *round-trip type checking*, which propagates goal types "through" elimination forms, allowing errors to be localized (i.e. found sooner) during type checking. In a synthesis context, failing sooner means avoiding costly search paths.

Example-based and logic-based specifications are complementary. Combining support for such specifications is another interesting direction for future work. It would be interesting to consider whether live bidirectional evaluation could help eliminate the inductive (i.e. trace-complete) requirement of partial specifications in Synquid, so that its powerful logic-based reasoning could better operate when given examples as partial specifications.

ACKNOWLEDGMENTS

The authors would like to thank Ian Voysey for guidance regarding proof strategies; Nadia Polikarpova, Brian Hempel, Michael Adams, Youyou Cong, and anonymous reviewers for many helpful suggestions; Aws Albarghouthi, John Feser, Viktor Kunčak, and Nadia Polikarpova for answering questions about Escher, λ^2 , Leon, and Synquid; and Robert Rand—who coined the name Myth—for suggesting the name Smyth, thus further entangling our work with its predecessor. This work was supported by NSF grants *Semantic Foundations for Hole-Driven Development* (CCF-1814900 and CCF-1817145) and *Direct Manipulation Programming Systems* (CCF-1651794).

A ADDITIONAL DEFINITIONS AND PROOFS

This section provides additional definitions for §3 and §4, as well as theorems and proofs.

A.1 Syntax

Datatypes. Rather than supporting arbitrary-arity constructors (as in the technical formulation of Osera and Zdancewic [2015]) we choose single-arity constructors and products (following the formulation by Frankle [2015]) to lighten the presentation of synthesis in §4.

Results. Figure 11 defines result classification.

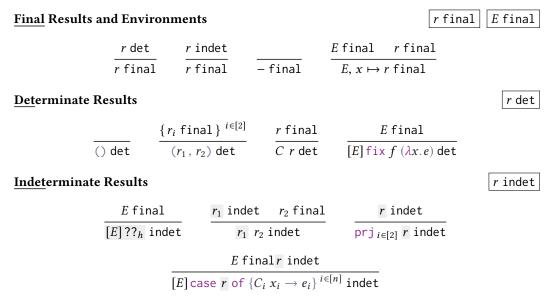

Fig. 11. Result Classification. Final results are determinate or indeterminate.

Examples. We define three simple functions below. The coercion $\lfloor v \rfloor$ "upcasts" a simple value to a result. The coercion $\lceil r \rceil = v$ "downcasts" a result to a simple value. The Filter(X) function removes top example constraints.

$$\frac{\lceil r_1 \rceil = v_1 \quad \lceil r_2 \rceil = v_2}{\lceil (r_1, r_2) \rceil = (v_1, v_2)} \quad \frac{\lceil r \rceil = v}{\lceil C \ r \rceil = C \ v}$$

$$Filter(X) = \{ (E \vdash \bullet \models ex) \in X \mid ex \neq \top \}$$

A.2 Type Checking

Figure 12 defines type checking for expressions, results, and examples. The result type checking Σ ; $\Delta \vdash r : T$ and example type checking Σ ; $\Delta \vdash ex : T$ judgements do not require a type context Γ because results and expressions do not contain free variables. Result typing refers to expression typing because function closures and case closures contain expressions and evaluation environments. Figure 13 defines type checking for constraints, solutions, programs, and assertions.

Expression Typing

$$\Sigma; \Delta; \Gamma \vdash e : T$$

$$\begin{array}{c} \text{[T-Fix]} \\ \underline{\Sigma\,;\,\Delta\,;\,\Gamma,\,f\,:\,T_1\to T_2,\,x\,:\,T_1\vdash e\,:\,T_2} \\ \underline{\Sigma\,;\,\Delta\,;\,\Gamma\vdash\,\text{fix}\,f\,\,(\lambda x.\,e)\,:\,T_1\to T_2} \end{array} \qquad \begin{array}{c} \text{[T-Var]} \\ \underline{\Gamma(x)=T} \\ \underline{\Sigma\,;\,\Delta\,;\,\Gamma\vdash x\,:\,T} \end{array} \qquad \begin{array}{c} \underline{\Gamma^{\text{HoLE}}} \\ \underline{\Delta(??_h)=(\Gamma\vdash\bullet:T)} \\ \underline{\Sigma\,;\,\Delta\,;\,\Gamma\vdash x\,:\,T} \end{array}$$

$$\frac{\text{[T-Unit]}}{\Sigma; \Delta; \Gamma \vdash () : ()} \qquad \frac{\left\{ \Sigma; \Delta; \Gamma \vdash e_i : T_i \right\}^{i \in [2]}}{\Sigma; \Delta; \Gamma \vdash (e_1, e_2) : (T_1, T_2)} \qquad \frac{\Sigma; \Delta; \Gamma \vdash C : T}{\Sigma; \Delta; \Gamma \vdash C : D}$$

 $\begin{array}{c} [\text{T-Case}] \\ \Sigma; \Delta; \Gamma \vdash e_1 : T_2 \rightarrow T \\ \Sigma; \Delta; \Gamma \vdash e_2 : T_2 \\ \hline \Sigma; \Delta; \Gamma \vdash e_1 \ e_2 : T \end{array} \qquad \begin{array}{c} [\text{T-Case}] \\ \Sigma; \Delta; \Gamma \vdash e : D \\ \Sigma(D) = \{C_i \ T_i\}^{i \in [n]} \\ \{\Sigma; \Delta; \Gamma \vdash e_i : T\}^{i \in [n]} \\ \hline \Sigma; \Delta; \Gamma \vdash e_1 \ e_2 : T \end{array} \qquad \begin{array}{c} \Sigma; \Delta; \Gamma \vdash e : D \\ \Sigma(D) = \{C_i \ T_i\}^{i \in [n]} \\ \{\Sigma; \Delta; \Gamma, x_i : T_i \vdash e_i : T\}^{i \in [n]} \\ \hline \Sigma; \Delta; \Gamma \vdash \text{case } e \text{ of } \{C_i \ x_i \rightarrow e_i\}^{i \in [n]} : T \end{array}$

Result Typing

$$\Sigma; \Delta \vdash r: T$$

$$\frac{\Sigma; \Delta \vdash E : \Gamma \qquad \Sigma; \Delta; \Gamma \vdash \text{fix } f (\lambda x. e) : T}{\Sigma; \Delta \vdash [E] \text{fix } f (\lambda x. e) : T} \qquad \frac{\Delta(??_h) = (\Gamma \vdash \bullet : T) \qquad \Sigma; \Delta \vdash E : \Gamma}{\Sigma; \Delta \vdash [E]??_h : T}$$

$$\frac{[\text{RT-PAIR}]}{[\text{RT-UNIT}]} \qquad \frac{[\text{RT-CTOR}]}{[\text{RT-CTOR}]} \qquad \frac{[\text{R$$

$$\frac{[\text{RT-Unit}]}{\Sigma; \Delta \vdash ():()} \qquad \frac{\{\Sigma; \Delta \vdash r_i : T_i\}^{i \in [2]}}{\Sigma; \Delta \vdash (r_1, r_2) : (T_1, T_2)} \qquad \frac{\Sigma(D)(C) = T \quad \Sigma; \Delta \vdash r : T}{\Sigma; \Delta \vdash C \quad r : D}$$

$$\begin{array}{lll} & & & & & & & & & \\ \Sigma; \Delta \vdash r_1 : T_2 \longrightarrow T & & & & & & \\ \Sigma; \Delta \vdash r_2 : T_2 & & & & & \\ \Sigma; \Delta \vdash r_1 : T_2 : T & & & & \\ \Sigma; \Delta \vdash r_2 : T & & & & \\ \hline \Sigma; \Delta \vdash r_1 : T_2 : T & & & \\ \hline \Sigma; \Delta \vdash r_2 : T_i & & & \\ \hline \Sigma; \Delta \vdash r_2 : T_i & & & \\ \hline \Sigma; \Delta \vdash r_2 : T_i & \\ \hline \Sigma; \Delta \vdash r_2 : T_i & & \\ \hline \Sigma; \Delta \vdash r_2 : T_i & & \\ \hline \Sigma; \Delta \vdash r_2$$

Environment Typing

$$\Sigma; \Delta \vdash E : \Gamma$$

$$\frac{\Sigma\,;\,\Delta \vdash E : \Gamma \qquad \Sigma\,;\,\Delta \vdash r : T}{\Sigma\,;\,\Delta \vdash (E,\,x \mapsto r) : (\Gamma,\,x : T)}$$

Example Typing

$$\Sigma\,;\Delta \vdash ex:T$$

$$\frac{[\text{XT-Pair}]}{\Sigma; \Delta \vdash () : ()} \quad \frac{\left\{ \Sigma; \Delta \vdash ex_i : T_i \right\}^{i \in [2]}}{\Sigma; \Delta \vdash (ex_1, ex_2) : (T_1, T_2)} \quad \frac{\Sigma(D)(C) = T \quad \Sigma; \Delta \vdash ex : T}{\Sigma; \Delta \vdash C \quad ex : D}$$

$$\frac{[\text{XT-Input-Output}]}{\Sigma; \Delta \vdash [v] : T_1 \quad \Sigma; \Delta \vdash ex : T_2} \quad \frac{[\text{XT-Top}]}{\Sigma; \Delta \vdash T}$$

Fig. 12. Expression, Result, and Example Type Checking.

Example, Unsolved Con., and Solution Typing
$$\Sigma$$
; $\Delta \vdash X : \Gamma$; T $\Sigma \vdash U : \Delta$ $\Sigma \vdash F : \Delta$

$$\begin{split} & \left\{ \begin{array}{l} \Sigma \,; \, \Delta \vdash E_i : \Gamma & \Sigma \,; \, \Delta \vdash ex_i : T \,\right\}^{\,i \in [n]} \\ \hline \Sigma \,; \, \Delta \vdash (E_1 \vdash \bullet \models ex_1), \, \ldots, \, (E_n \vdash \bullet \models ex_n) : \Gamma \,; \, T \\ \hline \\ & \left\{ \begin{array}{l} \Delta (??_{h_i}) = (\Gamma_i \vdash \bullet : T_i) & \Sigma \,; \, \Delta \vdash X_i : \Gamma_i \,; \, T_i \,\right\}^{\,i \in [n]} \\ \hline \Sigma \vdash (h_1 \longmapsto X_1, \, \ldots, \, h_n \longmapsto X_n) : \Delta \\ \hline \\ & \left\{ \begin{array}{l} \Delta (??_{h_i}) = (\Gamma_i \vdash \bullet : T_i) & \Sigma \,; \, \Delta \,; \, \Gamma_i \vdash e_i : T_i \,\right\}^{\,i \in [n]} \\ \hline \Sigma \vdash (h_1 \longmapsto e_1, \, \ldots, \, h_n \mapsto e_n) : \Delta \\ \hline \end{split}$$

Program and Assertion Typing

$$\begin{array}{ll} & \begin{array}{l} \Sigma; \Delta \vdash p : T \end{array} & \begin{array}{l} \Sigma; \Delta \vdash p : T; T' \end{array} \\ \hline \Sigma; \Delta \vdash \text{let main} = e \text{ in assert } (e_1 = e_2) : T; T' \\ \hline \Sigma; \Delta \vdash \text{let main} = e \text{ in assert } (e_1 = e_2) : T \end{array} \\ \hline \\ \frac{\Sigma; \Delta; -\vdash e : T}{\Sigma; \Delta \vdash \text{let main} = e \text{ in assert } (e_1 = e_2) : T} \\ \hline \\ \frac{\Sigma; \Delta; -\vdash e : T}{\Sigma; \Delta \vdash \text{let main} = e \text{ in assert } (e_1 = e_2) : T; T'} \\ \hline \\ \frac{\{\exists \, T \quad \Sigma; \Delta \vdash r_i : T \quad \Sigma; \Delta \vdash v_i : T\}^{i \in [n]}}{\Sigma \vdash \{r_i \Rightarrow v_i\}^{i \in [n]} : \Delta} \end{array}$$

Fig. 13. Constraint, Solution, Program, and Assertion Type Checking.

A.3 Type Soundness

The progress property is complicated by the fact that, in a big-step semantics, non-terminating computations are not necessarily distinguished from stuck ones [Leroy and Grall 2009]. Using a technique similar to that described by Ancona [2014], we augment evaluation with a natural k that limits the beta-reduction depth of an evaluation derivation. The augmented evaluation judgment $E \vdash e \Rightarrow_k r$ (Figure 14) asserts that evaluation produced a particular result or that it reached the specified depth before doing so.

Figure 14 shows how the evaluation judgment can be augmented to add fuel that limits the depth of beta reductions that can occur during evaluation. Note that for simplicity, the fuel is only depleted in recursive invocations that extend the environment. Also note that this relation is exactly the same as the ordinary evaluation relation, except for the beta-depth-limit k. As such, a progress theorem proven over this relation reflects the properties of the original evaluation relation.

Fig. 14. Augmented Evaluation with beta-depth limit. Only E-App and E-Case decrease the depth parameter.

THEOREM A.1 (DETERMINISM OF EVALUATION).

If $E \vdash e \Rightarrow r$ and $E \vdash e \Rightarrow r'$, then r = r'.

THEOREM A.2 (FINALITY OF EVALUATION).

If E final and $E \vdash e \Rightarrow r$, then r final.

Type checking and evaluation are related by the following properties.

THEOREM A.3 (Type Preservation).

If Σ ; Δ ; $\Gamma \vdash e : T$ and Σ ; $\Delta \vdash E : \Gamma$ and $E \vdash e \Rightarrow r$, then Σ ; $\Delta \vdash r : T$.

THEOREM A.4 (PROGRESS).

For all k, if Σ ; Δ ; $\Gamma \vdash e : T$ and Σ ; $\Delta \vdash E : \Gamma$, there exists r s.t. $E \vdash e \Rightarrow_k r$ and Σ ; $\Delta \vdash r : T$.

Proofs

THEOREM A.1, THEOREM A.2, and THEOREM A.3

Proof. Straightforward induction.

THEOREM A.4 (PROGRESS)

Proof. When k = 0, E-Limit will go through for any result. From the premise that e is well-typed $(\Sigma; \Delta; \Gamma \vdash e : T)$, it is straightforward to derive a result of the same type. When k > 0, the remaining cases go through by straightforward induction, thanks to the natural semantics.

A.4 Resumption

Figure 15 defines how to resume partially evaluated expressions. Resumption does not require an evaluation environment *E* because results do not contain free variables.

The definitions of R-Hole-Resume and R-Hole-Index below are slightly more complicated than the versions discussed in §3.3: to account for the Defer hole synthesis rule defined in §4.2, the rules below check whether F(h) equals $??_h$.

Fig. 15. Resumption.

П

```
THEOREM A.5 (DETERMINISM OF RESUMPTION). If F \vdash r \Rightarrow r and F \vdash r \Rightarrow r', then r = r'.
```

THEOREM A.6 (FINALITY OF RESUMPTION).

If
$$F \vdash r \Rightarrow r'$$
, then r' final.

THEOREM A.7 (Type Preservation of Resumption).

If
$$\Sigma \vdash F : \Delta$$
 and $\Sigma ; \Delta \vdash r : T$ and $F \vdash r \Rightarrow r'$, then $\Sigma ; \Delta \vdash r' : T$.

LEMMA A.8 (IDEMPOTENCY OF RESUMPTION).

If
$$F \vdash r_0 \Rightarrow r$$
, then $F \vdash r \Rightarrow r$.

LEMMA A.9 (SIMPLE VALUE RESUMPTION).

If
$$\lceil r \rceil = v$$
, then $F \vdash r \Rightarrow r$.

LEMMA A.10 (RESUMPTION OF APP OPERATOR).

If
$$F \vdash r_1 \Rightarrow r'_1$$
 and $F \vdash r'_1 \mid r_2 \Rightarrow r$, then $F \vdash r_1 \mid r_2 \Rightarrow r$.

LEMMA A.11 (RESUMPTION COMPOSITION).

If
$$F_1 \vdash r \Rightarrow r_1$$
 and $F_1 \oplus F_2 \vdash r_1 \Rightarrow r_2$, then $F_1 \oplus F_2 \vdash r \Rightarrow r_2$.

LEMMA A.12 (EVALUATION RESPECTS ENVIRONMENT RESUMPTION).

If
$$F_1 \vdash E \Rightarrow E'$$
 and $E \vdash e \Rightarrow r_1$ and $E' \vdash e \Rightarrow r_2$ and $F_1 \oplus F_2 \vdash r_1 \Rightarrow r_1'$ and $F_1 \oplus F_2 \vdash r_2 \Rightarrow r_2'$, then $r_1' = r_2'$.

Proofs

In the proofs below, we assume that evaluation and resumption are total. A priori, this assumption is unfounded; however, there are simple modifications we can make to SMYTH to ensure that this property holds. One approach described in [Osera 2015] is to annotate type contexts with tags that guarantee that all recursion is structurally decreasing (and thus terminating). This is the approach we used in our implementation of SMYTH. Moreover, the premise $e_h \neq ??_h$ of R-Hole-Resume ensures that resumption is total, even in the presence of the Defer synthesis rule.

This totality assumption is needed because otherwise the Refine-Fix rule could synthesize non-terminating functions which could then prevent evaluation (or resumption) from going through cleanly in the proof terms.

THEOREM A.5, THEOREM A.6, THEOREM A.7, THEOREM A.8, and THEOREM A.9

Proof. Straightforward induction.

THEOREM A.10 (RESUMPTION OF APP OPERATOR)

Proof.

▶ Given:

- (1) $F \vdash r_1 \Rightarrow r'_1$
- (2) $F \vdash r'_1 r_2 \Rightarrow r$

► Goal:

$$F \vdash r_1 \ r_2 \Rightarrow r$$

By inversion of resumption on (2), we get two cases.

Proc. ACM Program. Lang., Vol. 4, No. ICFP, Article 109. Publication date: August 2020.

► Case 1: *R-APP.*

(3)
$$F \vdash r_1' \Rightarrow r_1''$$

(4)
$$F \vdash r_2 \Rightarrow r_2'$$

(5)
$$r_1^{\prime\prime} = [E_f] \operatorname{fix} f(\lambda x. e_f)$$

(3)
$$F \vdash r'_1 \Rightarrow r''_1$$

(4) $F \vdash r_2 \Rightarrow r'_2$
(5) $r''_1 = [E_f] \text{ fix } f (\lambda x. e_f)$
(6) $E_f, f \mapsto r''_1, x \mapsto r'_2 \vdash e_f \Rightarrow r^*$
(7) $F \vdash r^* \Rightarrow r$
By Theorem A.8 on (1)

(7)
$$F \vdash r^* \Rightarrow r$$

(8)
$$F \vdash r'_1 \Rightarrow r'_1$$

By Theorem A.5 on (3) and (8) (9) $r'_1 = r''_1$

(9)
$$r_1' = r_1''$$

Goal is given by R-APP on (1) (observing (9)), (4), (5), (6), and (7).

► Case 2: *R-APP-INDET*.

(3)
$$F \vdash r_1' \Rightarrow r_1''$$

(4)
$$F \vdash r_2 \Rightarrow r_2'$$

(3)
$$F \vdash r_1 \Rightarrow r_1$$

(4) $F \vdash r_2 \Rightarrow r_2'$
(5) $r_1'' \neq [E] \text{ fix } f(\lambda x.e_f)$
By Theorem A.8 on (1)
(6) $F \vdash r_1' \Rightarrow r_1'$

(6)
$$F \vdash r'_1 \Rightarrow r'_2$$

By Theorem A.5 (Res. Det.) on (3) and (6) (7) $r'_1 = r''_1$

(7)
$$r_1' = r_1''$$

Goal is given by R-App-Indet on (1) (observing (7)), (4), and (5)

THEOREM A.11 (RESUMPTION COMPOSITION)

Proof. Most cases are trivial or go through by straightforward induction, along with the evaluation and resumption assumptions. The non-trivial cases are considered in detail here.

► Case 1: First premise through R-HOLE-RESUME.

(1)
$$F \vdash [E] ??_h \Rightarrow r'$$

(2)
$$F \oplus F' \vdash r' \Rightarrow r''$$

$$F \oplus F' \vdash [E] ??_h \Rightarrow r''$$

Because this is the case where (1) goes through R-Hole-Resume, we can, by inversion, establish the premises of R-Hole-Resume

- (3) F(h) = e
- (4) $e \neq ??_h$
- (5) $E \vdash e \Rightarrow r$
- (6) $F \vdash r \Rightarrow r'$

By the definition of \oplus , and (3)

(8)
$$(F \oplus F')(h) = e$$

By the induction hypothesis on (6) and (2)

(9)
$$F \oplus F' \vdash r \Rightarrow r''$$

Goal is given by R-Hole-Resume on (8), (5), and (9)

- ► Case 2: First premise through R-HOLE-INDET, second premise through R-HOLE-RESUME.
 - **▶** Given:
 - (1) $F \vdash [E] ??_h \Rightarrow r'$
 - (2) $F \oplus F' \vdash r' \Rightarrow r''$
 - ► Goal:

$$F \oplus F' \vdash [E] ??_h \Rightarrow r''$$

Because this is a case where (1) goes through R-Hole-Indet, we can, by inversion, establish the premises of R-Hole-Indet

- (3) $h \notin dom(F) \vee F(h) = ??_h$
- (4) $F \vdash E \Rightarrow E'$
- (5) $r' = [E']??_h$

Likewise, (2) goes through R-Hole-Resume (noting (5))

- (6) $(F \oplus F')(h) = e$
- (7) $E' \vdash e \Rightarrow r$
- (8) $F \oplus F' \vdash r \Rightarrow r''$

By the evaluation assumption

(9)
$$E \vdash e \Rightarrow r^*$$

By the resumption assumption

(10)
$$F \oplus F' \vdash r^* \Rightarrow r^+$$

By Theorem A.12 (Eval. Respects Env. Res.) on (4), (9), (7), (10), and (8)

(11)
$$r'' = r^+$$

Goal is given by R-Hole-Resume on (6), (9), and (10), observing (11)

► Case 3: First premise through R-APP.

▶ Given:

- (1) $F \vdash r_1 \ r_2 \Rightarrow r'$

► Goal:
$$F \oplus F' \vdash r_1 \ r_2 \Rightarrow r''$$

Because this is the case where the first premise goes through R-APP, we can, by inversion, establish the premises of R-App

- (3) $F \vdash r_1 \Rightarrow r'_1$
- (4) $F \vdash r_2 \Rightarrow r_2'$
- (5) $r'_1 = [E'_f] \operatorname{fix} f(\lambda x. e_f)$

(6)
$$E'_f$$
, $f \mapsto r'_1$, $x \mapsto r'_2 \vdash e_f \Rightarrow r^* j$ (7) $F \vdash r^* \Rightarrow r'$

By the resumption assumption

$$(8) \ F \oplus F' \vdash E'_f \Rightarrow E'^+_f$$

$$(9) \ F \oplus F' \vdash r_2' \Rightarrow r_2'^+$$

By R-Fix (observing (8))

$$(10) \ F \oplus F' \vdash [E'_f] \ \text{fix} \ f \ (\lambda x. e_f) \Rightarrow [E'^+_f] \ \text{fix} \ f \ (\lambda x. e_f)$$

By the definition of environment resumption, (8), (9), and (10)

$$\begin{array}{c} (11) \ F \oplus F' \vdash (E'_f, \ f \mapsto [E'_f] \ \text{fix} \ f \ (\lambda x.e_f), \ x \mapsto r'_2) \Rightarrow \\ (E'^+_f, \ f \mapsto [E'^+_f] \ \text{fix} \ f \ (\lambda x.e_f), \ x \mapsto r'^+_2) \end{array}$$

By the evaluation assumption

$$(12) \ (E_f'^+,\, f \mapsto [E_f'^+] \, \text{fix} \, f \, (\lambda x. e_f), \, x \mapsto r_2'^+) \vdash e_f \, \Rightarrow r^{*+}$$

By the induction hypothesis on (7) and (2)

(13)
$$F \oplus F' \vdash r^* \Rightarrow r''$$

By the resumption assumption

(14)
$$F \oplus F' \vdash r^{*+} \Rightarrow r^{*++}$$

By Theorem A.12 (Eval. Respects Env. Res.) on (11), (6), (12), (13), and (14)

(15)
$$r'' = r^{*++}$$

By the induction hypothesis on (3) and (10) (observing (5))

(16)
$$F \oplus F' \vdash r_1 \Rightarrow [E_f'^+] \operatorname{fix} f(\lambda x. e_f)$$

By the induction hypothesis on (4) and (9)

(17)
$$F \oplus F' \vdash r_2 \Rightarrow r_2'^+$$

By R-App on (16), (17), (trivial), (12), and (14)

$$(18) \ F \oplus F' \vdash r_1 \ r_2 \Rightarrow r^{*++}$$

The goal is given by combining (15) and (18)

► Case 4: First premise goes through R-CASE.

▶ Given:

(1)
$$F \vdash [E] \text{ case } r \text{ of } \{C_i \ x_i \rightarrow e_i\}^{i \in [n]} \Rightarrow r'$$

(2)
$$F \oplus F' \vdash r' \Rightarrow r''$$

► Goal:

$$F \oplus F' \vdash [E] \text{ case } r \text{ of } \{C_i \ x_i \rightarrow e_i\}^{i \in [n]} \Rightarrow r''$$

Because this is the case where the first premise goes through R-Case, we can, by inversion, establish the premises of R-Case

(3)
$$F \vdash r \Rightarrow C_j r'_i$$

(4)
$$F \vdash ([E] \lambda x_i.e_i) \ r'_i \Rightarrow r'$$

By inversion of resumption on (4), we find that (4) can only go through R-APP since the first argument is a syntactic fix (which by R-Fix will resume to a syntactic fix); so, by inversion, we can establish the premises of R-APP (to establish premises (5) and (6), we use inversion again)

(5)
$$F \vdash E \Rightarrow E'$$

(6)
$$F \vdash [E] \lambda x_i . e_i \Rightarrow [E'] \lambda x_i . e_i$$

(7)
$$F \vdash r'_i \Rightarrow r'_2$$

(8)
$$(E', x_i \mapsto r'_2) \vdash e_i \Rightarrow r^*$$

(9)
$$F \vdash r^* \Rightarrow r'$$

By R-CTOR on (7)

(10)
$$F \vdash C_j \ r'_j \Rightarrow C_j \ r'_2$$

By Theorem A.8 on (3)

(11)
$$F \vdash C_j \ r'_i \Rightarrow C_j \ r'_i$$

By Theorem A.5 (Res. Det.) on (10) and (11)

(12)
$$r'_j = r'_2$$

By the resumption assumption

(13)
$$F \oplus F' \vdash r'_i \Rightarrow r'^+_i$$

(14)
$$F \oplus F' \vdash E' \Rightarrow E'^+$$

By R-CTOR on (13)

(15)
$$F \oplus F' \vdash C_j \ r'_i \Rightarrow C_j \ r'^+_i$$

By the induction hypothesis on (3) and (15)

(16)
$$F \oplus F' \vdash r \Rightarrow C_j r_i'^+$$

By R-Fix on (14)

(17)
$$F \oplus F' \vdash [E'] \lambda x_j \cdot e_j \Rightarrow [E'^+] \lambda x_j \cdot e_j$$

By the induction hypothesis on (6) and (17)

(18)
$$F \oplus F' \vdash [E] \lambda x_i \cdot e_i \Rightarrow [E'^+] \lambda x_i \cdot e_i$$

By Theorem A.8 on (13)

$$(19) \ F \oplus F' \vdash r_j'^+ \Rightarrow r_j'^+$$

By the evaluation assumption

(20)
$$(E'^+, x_j \mapsto r_i'^+) \vdash e_j \Rightarrow r^{*+}$$

By the resumption assumption

(21)
$$F \oplus F' \vdash r^* \Rightarrow r^{*++}$$

(22)
$$F \oplus F' \vdash r^{*+} \Rightarrow r^{*\prime+}$$

By the definition of environment resumption, (14), and (13) (observing (12))

(23)
$$F \oplus F' \vdash (E', x_j \mapsto r'_2) \Rightarrow (E'^+, x_j \mapsto r'^+_j)$$

By Theorem A.12 (Eval. Respects Env. Res.) on (23), (8), (20), (21), and (22)

(24)
$$r^{*++} = r^{*\prime+}$$

By R-App on (18), (19), (trivial), (20), and (22) (observing (24))

(25)
$$F \oplus F' \vdash ([E] \lambda x_j . e_j) r_j'^+ \Rightarrow r^{*++}$$

By the induction hypothesis on (9) and (2)

(26)
$$F \oplus F' \vdash r^* \Rightarrow r''$$

By Theorem A.5 (Res. Det.) on (21) and (26)

(27)
$$r'' = r^{*++}$$

Goal is given by R-Case on (16) and (25) (observing (27))

► Case 5: First premise through R-Case-Indet, second premise through R-Case.

We use inversion to establish the premises of these rules as givens.

▶ Given:

- (1) $F \vdash r \Rightarrow r'$
- (2) $r' \neq C_j r_j$
- (3) $F + E \Rightarrow E'$
- (4) $F \vdash [E]$ case r of $\{C_i \ x_i \to e_i\}$ $i \in [n] \Rightarrow [E']$ case r' of $\{C_i \ x_i \to e_i\}$ $i \in [n]$
- (5) $F \oplus F' \vdash r' \Rightarrow C_j \ r'^+_j$
- (6) $F \oplus F' \vdash ([E'] \lambda x_j . e_j) \ r_i'^+ \Rightarrow r''$

► Goal:

$$F \oplus F' \vdash [E] \operatorname{case} r \operatorname{of} \left\{ C_i \ x_i \to e_i \right\}^{i \in [n]} \Rightarrow r''$$

By the resumption assumption

(7)
$$F \oplus F' \vdash E' \Rightarrow E'^+$$

(8)
$$F \oplus F' \vdash ([E'^+] \lambda x_j . e_j) \ r'^+_i \Rightarrow r''^+$$

By R-Fix on (7)

(9)
$$F \oplus F' \vdash [E'] \lambda x_j \cdot e_j \Rightarrow [E'^+] \lambda x_j \cdot e_j$$

By Theorem A.10 (Res. of App Op.) on (9) and (8)

(10)
$$F \oplus F' \vdash ([E'] \lambda x_j . e_j) r'^+_i \Rightarrow r''^+$$

By Theorem A.5 (Res. Det.) on (6) and (10)

(11)
$$r'' = r''^+$$

By the induction hypothesis on (3) and (7)

(12)
$$F \oplus F' \vdash E \Rightarrow E'^+$$

By R-Fix on (12)

(13)
$$F \vdash [E] \lambda x_i \cdot e_i \Rightarrow [E'^+] \lambda x_i \cdot e_i$$

By Theorem A.10 (Res. of App Op.) on (13) and (8) (observing (11)

(14)
$$F \oplus F' \vdash ([E] \lambda x_j . e_j) \ r_i'^+ \Rightarrow r''$$

By the induction hypothesis on (1) and (5)

(15)
$$F \oplus F' \vdash r \Rightarrow C_j \ r_j'^+$$

The goal is given by R-CASE on (15) and (14)

THEOREM A.12 (EVALUATION RESPECTS ENVIRONMENT RESUMPTION)

Proof. The E-Unit case is trivial. The cases for E-Ctor and E-Pair go through by straightforward induction, and likewise for E-Hole if the hole is filled. The unfilled case for E-Hole is analogous to the proof for the E-Fix case below. The remaining cases are considered in detail here.

► Case 1: *E-Fix.*

▶ Given:

- (1) $F \vdash E_1 \Rightarrow E_2$
- (2) $E_1 \vdash \text{fix } f(\lambda x.e) \Rightarrow r_1$
- (3) $E_2 \vdash \text{fix } f(\lambda x.e) \Rightarrow r_2$
- (4) $F \oplus F' \vdash r_1 \Rightarrow r'_1$
- (5) $F \oplus F' \vdash r_2 \Rightarrow r_2'$

► Goal:

$$r_1' = r_2'$$

By inversion of evaluation on (2)

(6)
$$r_1 = [E_1] \text{ fix } f(\lambda x. e)$$

By inversion of evaluation on (3)

(7)
$$r_2 = [E_2] \text{ fix } f(\lambda x. e)$$

By inversion of resumption on (6)

(8)
$$F \oplus F' \vdash E_1 \Rightarrow E'_1$$

(9)
$$r'_1 = [E'_1] \text{ fix } f(\lambda x.e)$$

By inversion of resumption on (7)

(10)
$$F \oplus F' \vdash E_2 \Rightarrow E'_2$$

(11)
$$r_2 = [E'_2] \text{ fix } f(\lambda x.e)$$

By Theorem A.11 (Res. Comp.) (across all bindings in environment) on (1) and (10)

(12)
$$F \oplus F' \vdash E_1 \Rightarrow E'_2$$

By Theorem A.5 (Res. Det.) (across all bindings in environment) on (8) and (12)

(13)
$$E_1' = E_2'$$

Observing (13), (9) and (11) equate to form the goal

► Case 2: E-VAR.

▶ Given:

- $(1) F \vdash E_1 \Rightarrow E_2$
 - (2) $E_1 \vdash x \Rightarrow r_1$
 - (3) $E_2 \vdash x \Rightarrow r_2$
- $(4) \ F \oplus F' \vdash r_1 \Rightarrow r'_1$
- (5) $F \oplus F' \vdash r_2 \Rightarrow r_2'$

► Goal:

$$r_1' = r_2'$$

By inversion of evaluation

- (6) $E_1(x) = r_1$
- (7) $E_2(x) = r_2$

By (1), (6), and (7)

(8) $F \vdash r_1 \Rightarrow r_2$

By Theorem A.11 (Res. Comp.) on (8) and (5)

(9)
$$F \oplus F' \vdash r_1 \Rightarrow r'_2$$

By Theorem A.5 (Res. Det.) on (4) and (9)

(Goal)
$$r'_1 = r'_2$$

For some expressions, evaluation can go through different rules, so the names of these cases will be given by the expression type rather than by the evaluation rule they go through.

► Case 3: Applications.

▶ Given:

- (1) $F \vdash E_1 \Rightarrow E_2$
- (2) $E_1 \vdash e_{fun} \ e_{arg} \Rightarrow r_1$
- (3) $E_2 \vdash e_{fun} \ e_{arg} \Rightarrow r_2$
- $(4) \ F \oplus F' \vdash r_1 \Rightarrow r_1'$
- $(5) F \oplus F' \vdash r_2 \Rightarrow r_2'$

► Goal:

$$r_1' = r_2'$$

By inversion of eval on (2) and (3), we get four subcases:

► Subcase 1: E-APP, E-APP.

(6)
$$E_1 \vdash e_{fun} \Rightarrow r_{fun1}$$

(7)
$$r_{fun1} = [E_{f1}] \text{ fix } f_1(\lambda x_1.e_{f1})$$

(8)
$$E_1 \vdash e_{arg} \Rightarrow r_{arg1}$$

(9)
$$(E_{f1}, f_1 \mapsto r_{fun1}, x_1 \mapsto r_{arg1}) \vdash e_{f1} \Rightarrow r_1$$

(10)
$$E_2 \vdash e_{fun} \Rightarrow r_{fun2}$$

(11)
$$r_{fun2} = [E_{f2}] \operatorname{fix} f_2(\lambda x_2.e_{f2})$$

(12)
$$E_2 \vdash e_{arg} \Rightarrow r_{arg2}$$

(13)
$$(E_{f2}, f_2 \mapsto r_{fun2}, x_2 \mapsto r_{arg2}) \vdash e_{f2} \Rightarrow r_2$$

By R-Fix (observing (7) and (11))

(14)
$$F \oplus F' \vdash E_{f1} \Rightarrow E'_{f1}$$

(15)
$$F \oplus F' \vdash r_{fun1} \Rightarrow [E'_{f1}] \operatorname{fix} f_1(\lambda x_1.e_{f1})$$

(16)
$$F \oplus F' \vdash E_{f2} \Rightarrow E'_{f2}$$

(17)
$$F \oplus F' \vdash r_{fun2} \Rightarrow [E'_{f2}] \operatorname{fix} f_2(\lambda x_2.e_{f2})$$

By the induction hypothesis on (1), (6), (10), (15), and (17)

(18)
$$[E'_{f1}]$$
 fix $f_1(\lambda x_1.e_{f1}) = [E'_{f2}]$ fix $f_2(\lambda x_2.e_{f2})$

By the resumption assumption

(19)
$$F \oplus F' \vdash r_{arg1} \Rightarrow r'_{arg1}$$

(20)
$$F \oplus F' \vdash r_{arg2} \Rightarrow r'_{arg2}$$

By the induction hypothesis on (1), (8), (12), (19), and (20)

(21)
$$r'_{arg1} = r'_{arg2}$$

By the definition of environment resumption, (16), (17), and (20)

$$(22) \ F \oplus F' \vdash (E_{f2}, \, f_2 \mapsto r_{fun2}, \, x_2 \mapsto r_{arg2}) \Rightarrow (E'_{f2}, \, f_2 \mapsto r_{fun2}, \, x_2 \mapsto r'_{arg2})$$

By the evaluation assumption

$$(23) \ (E'_{f2},\,f_2\mapsto [E'_{f2}]\,\mathrm{fix}\,f_2\,(\lambda x_2.e_{f2}),\,x_2\mapsto r'_{arg2})\vdash e_{f2}\Rightarrow r_2^*$$

By the resumption assumption

(24)
$$F \oplus F' \vdash r_2^* \Rightarrow r_2^{*'}$$

By the induction hypothesis on (22), (13), (23), (5), and (24)

(25)
$$r_2^{*\prime} = r_2^{\prime}$$

By the definition of environment resumption, (14), (18), (15), (19), and (21)

(26)
$$F \oplus F' \vdash (E_{f1}, f_1 \mapsto r_{fun1}, x_1 \mapsto r_{arg1}) \Rightarrow (E'_{f2}, f_2 \mapsto [E'_{f2}] \text{ fix } f_2 (\lambda x_2 \cdot e_{f2}), x_2 \mapsto r'_{arg2})$$

By the induction hypothesis on (26), (9) (noting (18)), (23), (4), and (24)

(27)
$$r_2^{*\prime} = r_1^{\prime}$$

Combining (25) and (27) gives the goal

► Subcase 2: *E-APP*, *E-APP-INDET*.

- (6) $E_1 \vdash e_{fun} \Rightarrow r_{fun1}$
- (7) $r_{fun1} = [E_{f1}] \text{ fix } f_1 (\lambda x_1.e_{f1})$
- (8) $E_1 \vdash e_{arg} \Rightarrow r_{arg1}$
- (9) $(E_{f1}, f_1 \mapsto r_{fun1}, x_1 \mapsto r_{arg1}) \vdash e_{f1} \Rightarrow r_1$
- (10) $r_2 = r_{fun2} r_{arg2}$
- (11) $E_2 \vdash e_{fun} \Rightarrow r_{fun2}$
- (12) $r_{fun2} \neq [E_{f2}] \text{ fix } f_2(\lambda x_2.e_{f2})$
- (13) $E_2 \vdash e_{arg} \Rightarrow r_{arg2}$

By R-Fix (observing (7))

(14)
$$F \oplus F' \vdash E_{f1} \Rightarrow E'_{f1}$$

(15)
$$F \oplus F' \vdash r_{fun1} \Rightarrow [E'_{f1}] \operatorname{fix} f_1(\lambda x_1.e_{f1})$$

By the resumption assumption

(16)
$$F \oplus F' \vdash r_{fun2} \Rightarrow r'_{fun2}$$

(17)
$$F \oplus F' \vdash r_{arg1} \Rightarrow r'_{arg1}$$

(18)
$$F \oplus F' \vdash r_{arg2} \Rightarrow r'_{arg2}$$

By the induction hypothesis on (1), (8), (13), (17), and (18)

(19)
$$r'_{arg1}=r'_{arg2}$$

By the induction hypothesis on (1), (6), (11), (15), and (16)

(20)
$$[E'_{f1}]$$
 fix $x_{f1}(\lambda x_1.e_{f1}) = r'_{fun2}$

By the evaluation assumption

(21)
$$(E'_{f1}, f \mapsto [E'_{f1}] \text{ fix } f_1(\lambda x_1.e_{f1}), x \mapsto r'_{arg1}) \vdash e_{f1} \Rightarrow r^*$$

By the resumption assumption

(22)
$$F \oplus F' \vdash r^* \Rightarrow r^{*'}$$

By R-App on (16), (18), (20), (21) (observing (19)), and (22)

(23)
$$F \oplus F' \vdash r_{fun2} \ r_{arg2} \Rightarrow r^{*'}$$

By Theorem A.5 (Determinism of Resumption) on (5) and (23)

(24)
$$r^{*\prime} = r_2'$$

By the definition of environment resumption, (14), (15), and (17)

$$(25) \ F \oplus F' \vdash (E_{f1}, \ f_1 \mapsto r_{fun1}, \ x_1 \mapsto r_{arg1}) \Rightarrow \\ (E'_{f1}, \ f_1 \mapsto [E'_{f1}] \ \text{fix} \ f_1 \ (\lambda x_1.e_{f1}), \ x_1 \mapsto r'_{arg1})$$

By the induction hypothesis on (25), (9), (21), (4), and (22)

(26)
$$r^{*\prime} = r_1'$$

Combining (24) and (26) gives the goal

► **Subcase 3:** *E-APP-INDET*, *E-APP*.

Analagous to previous case.

- ► Subcase 4: *E-App-Indet*, *E-App-Indet*.
 - (7) $E_1 \vdash e_{fun} \Rightarrow r_{fun1}$
 - (8) $r_{fun1} \neq [E_{f1}] \text{ fix } f_1(\lambda x_1.e_{f1})$
 - (9) $E \vdash e_{arg} \Rightarrow r_{arg1}$
 - (10) $r_2 = r_{fun2} \ r_{arg2}$
 - (11) $E_2 \vdash e_{fun} \Rightarrow r_{fun2}$
 - (12) $r_{fun2} \neq [E_{f2}] \text{ fix } f_2(\lambda x_2.e_{f2})$
 - (13) $E_2 \vdash e_{arg} \Rightarrow r_{arg2}$

By the resumption assumption

(14)
$$F \oplus F' \vdash r_{fun1} \Rightarrow r'_{fun1}$$

(15)
$$F \oplus F' \vdash r_{arg1} \Rightarrow r'_{arg1}$$

(16)
$$F \oplus F' \vdash r_{fun2} \Rightarrow r'_{fun2}$$

(17)
$$F \oplus F' \vdash r_{arg2} \Rightarrow r'_{arg2}$$

By the induction hypothesis on (1), (7), (11), (14), and (16)

(18)
$$r'_{fun1} = r'_{fun2}$$

By the induction hypothesis on (1), (9), (13), (15), and (17)

(19)
$$r'_{arg1} = r'_{arg2}$$

Resumption of r_1 and r_2 could go through R-APP or R-INDET, but in either case, the premises and conclusion are entirely determined by the resumptions of r_{fun1} and r_{fun2} , equated by (18), and r_{arg1} and r_{arg2} , equated by (19). As such, we can conclude that $r'_1 = r'_2$.

► Case 4: Projections.

Without loss of generality, we will only detail the prj_1 e case

▶ Given:

- (1) $F \vdash E_1 \Rightarrow E_2$
- (2) $E_1 \vdash \mathsf{prj}_1 \ e \Rightarrow r_1$
- (3) $E_2 \vdash \mathsf{prj}_1 \ e \Rightarrow r_2$
- $(4) \ F \oplus F' \vdash r_1 \Rightarrow r'_1$
- (5) $F \oplus F' \vdash r_2 \Rightarrow r'_2$

► Goal:

$$r_1' = r_2'$$

By inversion of evaluation on (2) and (3), we get four subcases:

- **► Subcase 1:** *E-Prj, E-Prj.*
 - (6) $E_1 \vdash e \Rightarrow (r_1, r_1^*)$
 - (7) $E_2 \vdash e \Rightarrow (r_2, r_2^*)$

By the resumption assumption

- (8) $F \oplus F' \vdash r_1^* \Rightarrow r_1^{*'}$
- $(9) F \oplus F' \vdash r_2^* \Rightarrow r_2^{*'}$

By R-Pair on (4) and (8)

(10)
$$F \oplus F' \vdash (r_1, r_1^*) \Rightarrow (r_1', r_1^{*'})$$

By R-PAIR on (5) and (9)

(11)
$$F \oplus F' \vdash (r_2, r_2^*) \Rightarrow (r_2', r_2^{*'})$$

By the induction hypothesis on (1), (6), (7), (10), and (11)

(12)
$$(r'_1, r''_1) = (r'_2, r''_2)$$

The goal follows from (12)

► Subcase 2: *E-Prj*, *E-Prj-INDET*.

(6)
$$E_1 \vdash e \Rightarrow (r_1, r_1^*)$$

(7)
$$r_2 = \text{prj}_1 r_2^*$$

(8)
$$E_2 \vdash e \Rightarrow r_2^*$$

(9)
$$r_2^* \neq (r_a, r_b)$$

By the resumption assumption

(10)
$$F \oplus F' \vdash r_1^* \Rightarrow r_1^{*'}$$

$$(11) \ F \oplus F' \vdash r_2^* \Rightarrow r_2^{*'}$$

By R-Pair on (4) and (10)

(12)
$$F \oplus F' \vdash (r_1, r_1^*) \Rightarrow (r_1', r_1^{*'})$$

By the induction hypothesis on (1), (6), (8), (12), and (11)

(13)
$$(r'_1, r_1^{*\prime}) = r_2^{*\prime}$$

By R-PRJ on (11) (observing (13) and (7))

(14)
$$F \oplus F' \vdash r_2 \Rightarrow r'_1$$

Theorem A.5 (Determinism of Resumption) combined with (5) and (14) yield the goal

► Subcase 3: *E-Prj-INDET*, *E-Prj.*

Analagous to previous case.

► Subcase 4: *E-Prj-INDET*, *E-Prj-INDET*.

(6)
$$r_1 = \text{prj}_1 r_1^*$$

(7)
$$E_1 \vdash e \Rightarrow r_1^*$$

(8)
$$r_1^* \neq (r_a, r_b)$$

(9)
$$r_2 = \text{prj}_1 r_2^*$$

(10)
$$E_2 \vdash e \Rightarrow r_2^*$$

(11)
$$r_2^* \neq (r_c, r_d)$$

By the resumption assumption

$$(12) \ F \oplus F' \vdash r_1^* \Rightarrow r_1^{*'}$$

(13)
$$F \oplus F' \vdash r_2^* \Rightarrow r_2^{*'}$$

By the induction hypothesis on (1), (7), (10), (12), and (13)

(14)
$$r_1^{*\prime} = r_2^{*\prime}$$

Resumption of r_1 and r_2 could go through R-PrJ or R-PrJ-INDET, but in either case, the premises and conclusion are entirely determined by the resumptions of r_1^* and r_2^* , equated by (14). As such, we can conclude that $r_1' = r_2'$

► Case 5: Case/Match.

▶ Given:

- (1) $F \vdash E_1 \Rightarrow E_2$
- (2) $E_1 \vdash \mathsf{case}\ e \ \mathsf{of}\ \{C_i\ x_i \to e_i\}^{\ i \in [n]} \Rightarrow r_1$
- (3) $E_1 \vdash \mathsf{case}\ e\ \mathsf{of}\ \{C_i\ x_i \to e_i\}^{\ i \in [n]} \Rightarrow r_2$
- (4) $F \oplus F' \vdash r_1 \Rightarrow r'_1$
- (5) $F \oplus F' \vdash r_2 \Rightarrow r'_2$

► Goal:

$$r_1' = r_2'$$

By inversion of evaluation on (2) and (3), we get four subcases:

- **► Subcase 1:** *E-CASE*, *E-CASE*.
 - (6) $E_1 \vdash e \Rightarrow C_{j_1} r_1^*$ (for some $j_1 < n$)
 - (7) $(E_1, x_{i_1} \mapsto r_1^*) \vdash e_{i_1} \Rightarrow r_1$
 - (8) $E_2 \vdash e \Rightarrow C_{j_2} r_2^*$ (for some $j_2 < n$)
 - (9) $(E_2, x_{i_2} \mapsto r_2^*) \vdash e_{i_2} \Rightarrow r_2$

By the resumption assumption

- (10) $F \oplus F' \vdash r_1^* \Rightarrow r_1^{*'}$
- (11) $F \oplus F' \vdash r_2^* \Rightarrow r_2^{*'}$

By R-CTOR on (10)

(12)
$$F \oplus F' \vdash C_{j_1} \ r_1^* \Rightarrow C_{j_1} \ r_1^{*'}$$

By R-CTOR on (11)

(13)
$$F \oplus F' \vdash C_{i_2} \ r_2^* \Rightarrow C_{i_2} \ r_2^{*'}$$

By the induction hypothesis on (1), (6), (8), (12), and (13)

(14)
$$C_{i_1} r_1^{*\prime} = C_{i_2} r_2^{*\prime}$$

By (14),
$$C_{i_1} = C_{i_2}$$
.

Each constructor of a given type is unique, so $j_1 = j_2$, and thus

$$x_{i_1} = x_{i_2}$$
 and $e_{i_1} = e_{i_2}$.

By the resumption assumption

(15)
$$F \oplus F' \vdash E_2 \Rightarrow E'_2$$

By Theorem A.11 (Res. Comp.) (across all bindings in environment) on (1) and (15)

(16)
$$F \oplus F' \vdash E_1 \Rightarrow E'_2$$

By the evaluation assumption

(17)
$$(E'_2, x_{j_2} \mapsto r_2^{*'}) \vdash e_{j_2} \Rightarrow r^*$$

By the resumption assumption

(18)
$$F \oplus F' \vdash r^* \Rightarrow r^{*'}$$

By the definition of environment resumption, (16), (10), and (14)

(19)
$$F \oplus F' \vdash (E_1, x_{j_1} \mapsto r_1^*) \Rightarrow (E'_2, x_{j_2} \mapsto r_2^{*'})$$

By the induction hypothesis on (19), (7), (17), (4), and (18)

(20)
$$r^{*\prime} = r_1'$$

By the definition of environment resumption, (15), and (11)

(21)
$$F \oplus F' \vdash (E_2, x_{j_2} \mapsto r_2^*) \Rightarrow (E'_2, x_{j_2} \mapsto r_2^{*'})$$

By the induction hypothesis on (21), (9), (17), (5), and (18)

(22)
$$r^{*\prime} = r_2'$$

Combining (20) and (22) gives the goal

► Subcase 2: *E-CASE*, *E-CASE-INDET*.

(6)
$$E_1 \vdash e \Rightarrow C_{j_1} r_1^*$$
 (for some $j_1 < n$)

(7)
$$(E_1, x_{j_1} \mapsto r_1^*) \vdash e_{j_1} \Rightarrow r_1$$

(8)
$$E_2 \vdash e \Rightarrow r_2^*$$

(9)
$$r_2^* \neq C_j \ r_j$$

(10)
$$r_2 = [E_2] \operatorname{case} r_2^* \operatorname{of} \{C_i \ x_i \to e_i\}^{i \in [n]}$$

By the resumption assumption

(11)
$$F \oplus F' \vdash r_1^* \Rightarrow r_1^{*'}$$

$$(12) \ F \oplus F' \vdash r_2^* \Rightarrow r_2^{*'}$$

$$(13) \ F \oplus F' \vdash E_2 \Rightarrow E'_2$$

By R-CTOR on (11)

(14)
$$F \oplus F' \vdash C_{j_1} \ r_1^* \Rightarrow C_{j_1} \ r_1^{*'}$$

By the induction hypothesis on (1), (6), (8), (14), and (12)

(15)
$$C_{j_1} r_1^{*\prime} = r_2^{*\prime}$$

By R-Fix on (13)

(16)
$$F \oplus F' \vdash [E_2] \text{ fix } f_{j_1}(\lambda x_{j_1}.e_{j_1}) \Rightarrow [E'_2] \text{ fix } f_{j_1}(\lambda x_{j_1}.e_{j_1})$$

By Theorem A.8 (Idempotency of Resumption) on (11)

(17)
$$F \oplus F' \vdash r_1^{*'} \Rightarrow r_1^{*'}$$

By the evaluation assumption

(18)
$$(E'_2, x_{i_1} \mapsto r_1^{*'}) \vdash e_{i_1} \Rightarrow r^*$$

By the resumption assumption

(19)
$$F \oplus F' \vdash r^* \Rightarrow r^{*'}$$

By R-App on (16), (17), (trivial), (18), and (19)

(20)
$$F \oplus F' \vdash ([E_2] \text{ fix } f_{i_1} (\lambda x_{i_1} \cdot e_{i_1})) \ r_1^{*'} \Rightarrow r^{*'}$$

By R-Case on (12) (noting (15)) and (20)

(21)
$$F \oplus F' \vdash r_2 \Rightarrow r^{*'}$$

By Theorem A.5 (Determinism of Resumption) on (5) and (21)

(22)
$$r^{*\prime} = r_2'$$

By Theorem A.11 (Res. Comp.) (across all bindings in environment) on (1) and (13)

(23)
$$F \oplus F' \vdash E_1 \Rightarrow E'_2$$

By the definition of environment resumption, (23), and (11)

(24)
$$F \oplus F' \vdash (E_1, x_{i_1} \mapsto r_1^*) \Rightarrow (E'_2, x_{i_1} \mapsto r_1^*)$$

By the induction hypothesis on (24), (7), (18), (4), and (19)

(25)
$$r^{*\prime} = r'_1$$

Combining (22) and (25) gives the goal

► Subcase 3: E-CASE-INDET, E-CASE.

Analagous to previous case.

► Subcase 4: *E-Case-Indet*, *E-Case-Indet*.

(6)
$$E_1 \vdash e \Rightarrow r_1^*$$

(7)
$$r_{i}^{*} \neq C_{i} r_{i}$$

(8)
$$r_1 = [E_1] \operatorname{case} r_1^* \operatorname{of} \{C_i \ x_i \to e_i\}^{i \in [n]}$$

$$(9) E_2 \vdash e \implies r_2^*$$

(10)
$$r_2^* \neq C_j r_j$$

(11)
$$r_2 = [E_2] \operatorname{case} r_2^* \operatorname{of} \{C_i \ x_i \to e_i\}^{i \in [n]}$$

By the resumption assumption

(12)
$$F \oplus F' \vdash r_1^* \Rightarrow r_1^{*'}$$

(13)
$$F \oplus F' \vdash r_2^* \Rightarrow r_2^{*'}$$

By the induction hypothesis on (1), (6), (8), (12), and (13)

(14)
$$r_1^{*\prime} = r_2^{*\prime}$$

By the resumption assumption

(15)
$$F \oplus F' \vdash E_2 \Rightarrow E'_2$$

By Theorem A.11 (Res. Comp.) (across all bindings in environment) on (1) and (15)

(16)
$$F \oplus F' \vdash E_1 \Rightarrow E'_2$$

Resumption of r_1 and r_2 could go through either R-Case or R-Case-Indet. For R-Case, all aspects of the premises and conclusion depend only on the resumptions of r_1^* and r_2^* —which are equated by (14)—except for the E in the premise $F \vdash ([E] \lambda x_j.e_j)$ $r' \Rightarrow r'_j$. Noting R-Fix, this premise must go through R-App, whose premises and conclusions are entirely dependent on the resumptions of the operands r_1 r_2 . By R-Fix, (15), and (16), the resumptions of $[E_1]$ fix f_j ($\lambda x_j.e_j$) and $[E_2]$ fix f_j ($\lambda x_j.e_j$) are equal. The situation for R-Case-Indet is similar, though simpler, since its premises and conclusion depend only on the resumptions of r_1^* and r_2^* and the resumptions of E_1 and E_2 , which are equated by (15) and (16). Since the resumptions of r_1 and r_2 (i.e. r'_1 and r'_2) depend entirely on values which are equated, they must themselves be equated.

A.5 Unevaluation Constraint Merging

Figure 16 defines the merge operations for constraints.

(Syntactic) Constraint Merging
$$F_1 \oplus F_2 = F \quad U_1 \oplus U_2 = U \quad K_1 \oplus K_2 = K$$

$$\frac{\forall ??_h \in dom(F_1) \cap dom(F_2). \ F_1(??_h) = F_2(??_h)}{F_1 \oplus F_2 = F_1 + F_2}$$

$$U_1' = U_1 \setminus dom(U_2) \qquad U_2' = U_2 \setminus dom(U_1)$$

$$U_{1}' = U_{1} \setminus dom(U_{2}) \qquad U_{2}' = U_{2} \setminus dom(U_{1})$$

$$U_{12} = \{ h \mapsto U_{1}(??_{h}) + U_{2}(??_{h}) \mid ??_{h} \in dom(F_{1}) \cap dom(F_{2}) \}$$

$$U_{1} \oplus U_{2} = U_{1}' + U_{12} + U_{2}'$$

$$\frac{F_{1} \oplus F_{2} = F' \qquad U_{1} \oplus U_{2} = U'}{(U_{1}; F_{1}) \oplus (U_{2}; F_{2}) = (U'; F')}$$

(Semantic) Constraint Merging

$$\Sigma$$
; Δ ; $Merge(K) \triangleright K'$

$$F(??_{h}) = e \qquad \Sigma; \Delta; F \vdash e \rightleftharpoons X \dashv K \qquad \qquad ??_{h} \notin F$$

$$\Sigma; \Delta; Resolve(h \mapsto X; F) \rightsquigarrow K \qquad \Sigma; \Delta; Resolve(h \mapsto X; F) \rightsquigarrow (h \mapsto X; -1)$$

$$\{\Sigma; \Delta; Resolve(h_{i} \mapsto X; F) \rightsquigarrow K'_{i}\}^{i \in [n]}$$

$$\Sigma; \Delta; Step(h_{1} \mapsto X_{1}, \dots, h_{n} \mapsto X_{n}; F) \rightsquigarrow (-; F) \oplus K'_{1} \oplus \dots \oplus K'_{n}$$

$$\Sigma; \Delta; Step(K) \rightsquigarrow K' \qquad K \neq K'$$

$$\Sigma; \Delta; Merge(K') \rhd K'' \qquad \Sigma; \Delta; Merge(K) \rhd K' \qquad \Sigma; \Delta; Merge(K) \rhd K'$$

Fig. 16. Constraint Merging.

A.6 Type-Directed Guessing

Figure 17 defines type-directed guessing rules analogous to expression type rules (Figure 12).

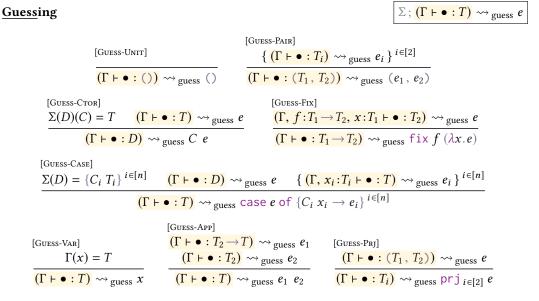

Fig. 17. Type-Directed Guessing.

Guessing Recursive Sketches. Guessing does not generate hole expressions. Guessing is, furthermore, limited to small terms and elimination forms in practice. However, if guessing were to generate recursive function sketches, the Guess-and-Check rule provides an additional anti-dote for trace-completeness: when guessing an expression fix $f(\lambda x.e)$ to fill ??h, the extended hole-filling F, $h \mapsto \text{fix } f(\lambda x.e)$ "ties the recursive knot" before checking example consistency.

A.7 Synthesis Soundness

```
THEOREM A.13 (Type Soundness of Unevaluation).

If \Sigma \vdash F' : \Lambda and \Sigma : \Lambda \vdash F : T and \Sigma : \Lambda \vdash g : T and
```

If
$$\Sigma \vdash F' : \Delta$$
 and $\Sigma ; \Delta \vdash r : T$ and $\Sigma ; \Delta \vdash ex : T$ and $F' \vdash r \Leftarrow ex \dashv (U, F)$, then $\Sigma \vdash U : \Delta$ and $\Sigma \vdash F : \Delta$.

THEOREM A.14 (Type Soundness of Checking).

If
$$\Sigma \vdash F' : \Delta$$
 and $\Sigma ; \Delta \vdash X : \Gamma ; T$ and $\Sigma ; \Delta ; \Gamma \vdash e : T$ and $F' \vdash e \rightleftharpoons X \dashv (U, F)$, then $\Sigma \vdash U : \Delta$ and $\Sigma \vdash F : \Delta$.

THEOREM A.15 (Type Soundness of Guess).

If
$$\Sigma$$
; $(\Gamma \vdash \bullet : T) \leadsto_{guess} e$, then Σ ; Δ ; $\Gamma \vdash e : T$.

THEOREM A.16 (Type Soundness of Refine/Branch).

If
$$\Sigma : \Delta \vdash X : \Gamma : T$$
 and $\Sigma \vdash F' : \Delta$
and $F' : (\Gamma \vdash \bullet : X \models T) \leadsto_{\{refine, branch\}} e \dashv \{ (\Gamma_i \vdash \bullet_{h_i} : T_i \models X_i) \}^{i \in [n]} : (U, F),$
then $\Sigma : \Delta + \{h_i \mapsto (\Gamma_i \vdash \bullet : T_i) \}^{i \in [n]} : \Gamma \vdash e : T$ and $\Sigma : \Delta \vdash X_i : \Gamma_i : T_i$.
and $\Sigma \vdash U : \Delta$ and $\Sigma \vdash F : \Delta$

THEOREM A.17 (Type Soundness of Fill).

If
$$\Sigma \vdash F' : \Delta$$
 and $\Sigma ; \Delta \vdash X : \Gamma ; T$ and $\Sigma ; \Delta ; F' ; (\Gamma \vdash \bullet_h : T \models X) \rightsquigarrow_{fill} (U ; F) ; \Delta'$
then $\Sigma \vdash (U, F) : \Delta + \Delta' + (h \mapsto (\Gamma \vdash \bullet : T))$.

THEOREM A.18 (Type Soundness of Result Consistency).

If
$$\Sigma$$
; $\Delta \vdash r : T$ and Σ ; $\Delta \vdash r' : T$ and $r \equiv_A r'$ then $\Sigma \vdash A : \Delta$.

THEOREM A.19 (Type Soundness of Simplify).

If
$$\Sigma \vdash A : \Delta$$
 and Simplify $(A) \triangleright (U, F)$, then $\Sigma \vdash U : \Delta$ and $\Sigma \vdash F : \Delta$.

THEOREM A.20 (Type Soundness of Program Evaluation).

If
$$\Sigma$$
; $\Delta \vdash p : T$; T' and $p \Rightarrow r$; A , then Σ ; $\Delta \vdash r : T$ and $\Sigma \vdash A : \Delta$.

THEOREM A.21 (SOUNDNESS OF EXAMPLE UNEVALUATION).

If
$$F \oplus F' \models K$$
 and r final and $F \vdash r \Leftarrow ex \dashv K$ and $F \oplus F' \vdash r \Rightarrow r'$ then $F \oplus F' \vdash r' \models ex$.

THEOREM A.22 (SOUNDNESS OF LIVE BIDIRECTIONAL EXAMPLE CHECKING).

If
$$F \oplus F' \models K$$
 and $F \vdash e \rightleftharpoons X \dashv K$, then $F \oplus F' \vdash e \models X$.

Theorem A.23 (Example Soundness of Refine).

If
$$\Sigma$$
; Δ ; $\Gamma \vdash \bullet : T \models X$ \leadsto refine $e \dashv \{ (\Gamma_i \vdash \bullet_{h_i} : T_i \models X_i) \}^{i \in [n]}$ and $\{F \vdash ??_{h_i} \models X_i\}^{i \in [n]}$, then $F \vdash e \models X$.

THEOREM A.24 (EXAMPLE SOUNDNESS OF BRANCH).

If
$$\Sigma$$
; Δ ; F ; $(\Gamma \vdash \bullet : T \models X) \leadsto_{branch} e \dashv \{ (\Gamma_i \vdash \bullet_{h_i} : T_i \models X_i) \}^{i \in [n]}$; K and $F \oplus F' \models K$ and $\{F \oplus F' \vdash ??_{h_i} \models X_i \}^{i \in [n]}$, then $F \oplus F' \vdash e \models X$.

THEOREM A.25 (EXAMPLE SOUNDNESS OF FILL).

If
$$\Sigma$$
; Δ ; F ; $(\Gamma \vdash \bullet_h : T \models X) \leadsto_{fill} K$; Δ' and $F \oplus F' \models K$, then $(F \oplus F')$ (?? $_h$) = e and $F \oplus F' \vdash e \models X$.

THEOREM A.26 (Type Soundness of Semantic Merge).

If
$$\Sigma \vdash K : \Delta$$
 and $\Sigma ; \Delta ; Merge(K) \triangleright K'$, then $\Sigma \vdash K' : \Delta$.

THEOREM A.27 (EXAMPLE SOUNDNESS OF SEMANTIC MERGE).

If
$$F \models K'$$
 and $\Sigma \in \Delta \in Merge(K) \triangleright K'$, then $F \models K$.

```
Theorem A.28 (Soundness of Solve).
```

If
$$\Sigma \vdash U : \Delta$$
 and $\Sigma \vdash F : \Delta$ and $\Sigma \not \subseteq \Delta$; Solve $(U, F) \leadsto F' \not \subseteq \Delta'$, then $\Sigma \vdash F' : \Delta'$ and $F' \models (U, F)$.

THEOREM A.29 (SOUNDNESS OF ASSERTION SIMPLIFICATION).

If
$$Simplify(A) > K$$
 and $F \models K$, then $F \models A$.

THEOREM A.30 (SOUNDNESS OF SYNTHESIS).

```
If \Sigma; \Delta \vdash p : T; T' and p \Rightarrow r; A and Simplify(A) <math>\triangleright K and \Sigma; \Delta; Solve(K) \leadsto F; \Delta', then \Sigma \vdash F : \Delta' and F \models A.
```

LEMMA A.31 (EXAMPLE SATISFACTION OF SIMPLE VALUE).

If
$$\lceil ex \rceil = v$$
 and $F \vdash r \models ex$, then $\lceil r \rceil = v$.

LEMMA A.32 (CONSTRAINT SATISFACTION IMPLIES COMPLETE RESUMPTION).

```
If \lceil ex \rceil = v and r final and - \vdash r \Leftarrow ex \dashv K and F \models K, then F \vdash r \Rightarrow r' and \lceil r' \rceil = v.
```

Proofs

THEOREM A.13 (UNEVAL) and THEOREM A.14 (CHECK)	
Proof. Straightforward mutual induction.	
Гнеоrem A.15 (Guess)	
Proof. Straightforward induction.	
Гнеогем А.16 (Refine/Branch)	
Proof. Straightforward by way of Theorem A.15, Theorem A.3, and Theorem A.14.	
Гнеоrem A.17 (Fill)	
Proof. The Defer case is trivial. The Refine,Вranch case is straightforward by way rem A.16. The Guess-And-Снеск case goes through by Theorem A.14.	of Theo
THEOREM A.18 (RESULT CONSISTENCY)	
Proof. Straightforward induction.	
THEOREM A.19 (SIMPLIFY)	
Proof. Straightforward by way of Theorem A.13.	
Гнеогем А.20 (Program evaluation)	
<i>Proof.</i> Straightforward by way of Theorem A.3 and Theorem A.18.	

Proof. The cases U-Top, U-Unit, U-Pair and U-Ctor are straightforward applications of their respective XS rules and induction. U-Hole goes through because the premise $F \oplus F' \models K$ proves example satisfaction for the single generated constraint. The remaining cases are considered in detail here.

Proc. ACM Program. Lang., Vol. 4, No. ICFP, Article 109. Publication date: August 2020.

THEOREM A.21 (SOUNDNESS OF EXAMPLE UNEVALUATION)

► Case 1: U-Fix.

- **▶** Given:
 - (1) $F \oplus F' \models K$
 - (2) [E] fix $f(\lambda x.e)$ final
 - (3) $F \vdash [E] \text{ fix } f(\lambda x.e) \leftarrow \{v \rightarrow ex\} \dashv K$
 - (4) $F \oplus F' \vdash [E] \text{ fix } f(\lambda x.e) \Rightarrow r'$

► Goal:

$$F \oplus F' \vdash r' \models \{v \rightarrow ex\}$$

By inversion of unevaluation on (3)

(5)
$$F \vdash e \rightleftharpoons ((E, f \mapsto [E] \text{ fix } f (\lambda x.e), x \mapsto v) \vdash \bullet \models ex) \dashv K$$

By inversion of the check judgment on (5)

(6)
$$(E, f \mapsto [E] \text{ fix } f(\lambda x.e), x \mapsto v) \vdash e \Rightarrow r^*$$

- (7) $F \vdash r^* \Rightarrow r^{**}$
- (8) $F \vdash r^{**} \Leftarrow ex \dashv K$

By the resumption assumption

(9)
$$F \oplus F' \vdash r^{**} \Rightarrow r^{**+}$$

By Theorem A.11 (Res. Comp.) on (7) and (9)

(10)
$$F \oplus F' \vdash r^* \Rightarrow r^{**+}$$

By the induction hypothesis on (1), Theorem A.6, (8), and (9)

(11)
$$F \oplus F' \vdash r^{**+} \models ex$$

By inversion of resumption on (4)

- (12) $F \oplus F' \vdash E \Rightarrow E'$
- (13) $r' = [E'] \operatorname{fix} f(\lambda x.e)$

By the evaluation assumption

(14)
$$(E', f \mapsto [E'] \text{ fix } f(\lambda x.e), x \mapsto v) \vdash e \Rightarrow r^{*'}$$

By Theorem A.9 (Simple Value Resumption)

(15)
$$F \oplus F' \vdash v \Rightarrow v$$

By the resumption assumption

(16)
$$F \oplus F' \vdash r^{*'} \Rightarrow r^{*''}$$

By Theorem A.8 (Idempotency of Resumption) on (4)

(17)
$$F \oplus F' \vdash [E'] \text{ fix } f(\lambda x.e) \Rightarrow [E'] \text{ fix } f(\lambda x.e)$$

By R-App on (17), (15), (13), (14), and (16)

(18)
$$F \oplus F' \vdash ([E'] \text{ fix } f(\lambda x.e)) \ v \Rightarrow r^{*''}$$

By the definition of environment resumption, (12), (4), and (15)

(19)
$$F \oplus F' \vdash (E, f \mapsto [E] \text{ fix } f(\lambda x.e), x \mapsto v) \Rightarrow (E', f \mapsto [E'] \text{ fix } f(\lambda x.e), x \mapsto v)$$

By Theorem A.12 (Eval. Respects Env. Res.) on (19), (6), (14), (10), and (16)

(20)
$$r^{**+} = r^{*''}$$

By XS-Input-Output on (18), (20), and (11)

(21)
$$F \oplus F' \vdash [E'] \text{ fix } f(\lambda x.e) \models \{v \rightarrow ex\}$$

Observing (13), (21) is the goal

► Case 2: *U-App.*

- **▶** Given:
 - (1) $F \oplus F' \models K$
 - (2) $(r_1 r_2)$ final
 - (3) $F \vdash r_1 \ r_2 \Leftarrow ex \dashv K$
 - (4) $F \oplus F' \vdash r_1 \ r_2 \Rightarrow r'$

► Goal:

$$F \oplus F' \vdash r' \models ex$$

By inversion of unevaluation on (3)

- (5) $[r_2] = v_2$
- (6) $F \vdash r_1 \Leftarrow \{v_2 \rightarrow ex\} \dashv K$

By the resumption assumption

(7)
$$F \oplus F' \vdash r_1 \Rightarrow r'_1$$

By the induction hypothesis on (1), inversion of final on (2), (6) and (7)

(8)
$$F \oplus F' \vdash r'_1 \models \{v_2 \rightarrow ex\}$$

By inversion of example satisfaction on (8)

- (9) $F \oplus F' \vdash r'_1 r_2 \Rightarrow r$
- (10) $F \oplus F' \vdash r \models ex$

By Theorem A.10 (Res. App. Op.) on (7) and (9)

$$(11) \quad F \oplus F' \vdash r_1 \quad r_2 \Rightarrow r$$

By Theorem A.5 (Determinism of Resumption) on (4) and (11)

(12)
$$r = r'$$

Goal is given by (10), observing (12)

► Case 3: Projections.

Without loss of generality, we will only detail the U-PRJ-1 case

- (1) $F \oplus F' \models K$
- (2) $(prj_1 r) final$
- (3) $F \vdash \operatorname{prj}_1 r \Leftarrow ex \dashv K$
- $(4) \quad F \oplus F' \vdash \mathsf{prj}_1 \ r \Rightarrow r'$

► Goal:

$$F \oplus F' \vdash r' \models ex$$

By inversion of unevaluation on (3)

(5)
$$F \vdash r \Leftarrow (ex, \top) \dashv K$$

By the resumption assumption

(6)
$$F \oplus F' \vdash r \Rightarrow r^+$$

By the induction hypothesis on (1), inversion of final on (2), (5), and (6)

(7)
$$F \oplus F' \vdash r^+ \models (ex, \top)$$

By inversion of example satisfaction on (7)

(8)
$$r^+ = (r_1^+, r_2^+)$$

$$(9) \quad F \oplus F' \vdash r_1^+ \models ex$$

By R-PRJ on (6) (observing (8))

(10)
$$F \oplus F' \vdash \operatorname{prj}_1 r \Rightarrow r_1^+$$

By Theorem A.5 (Determinism of Resumption) on (4) and (10)

(11)
$$r' = r_1^+$$

Goal is given by (9), observing (11)

► Case 4: U-CASE.

Given: (1)
$$F \oplus F' \models K_1 \oplus K_2$$

(2) ([
$$E$$
] case r of $\{C_i \ x_i \rightarrow e_i\}^{i \in [n]}$) final

(3)
$$F \vdash [E]$$
 case r of $\{C_i \ x_i \to e_i\}^{i \in [n]} \Leftarrow ex \dashv K_1 \oplus K_2$
(4) $F \oplus F' \vdash [E]$ case r of $\{C_i \ x_i \to e_i\}^{i \in [n]} \Rightarrow r'$

(4)
$$F \oplus F' \vdash [E] \text{ case } r \text{ of } \{C_i \mid x_i \rightarrow e_i\} \mid i \in [n] \Rightarrow r$$

► Goal:

$$F \oplus F' \vdash r' \models ex$$

By inversion of unevaluation on (3), going through U-Case

(5)
$$F \vdash r \Leftarrow C_i \top \dashv K_1$$

(6)
$$F \vdash e_j \rightleftharpoons ((E, x_j \mapsto C_j^{-1} r) \vdash \bullet \models ex) \dashv K_2$$

By inversion of checking on (6)

(7)
$$(E, x_i \mapsto C_i^{-1} r) \vdash e_i \Rightarrow r_0$$

(8)
$$F \vdash r_0 \Rightarrow r'_0$$

$$(9) F \vdash r_0' \Leftarrow ex \dashv K_2$$

By Theorem A.6 on (8)

(10)
$$r_0'$$
 final

By the resumption assumption

$$(11) \quad F \oplus F' \vdash r'_0 \Rightarrow r_0^{+'}$$

$$(12) \quad F \oplus F' \vdash r \Rightarrow r^+$$

By the induction hypothesis on (1), (10), (9), and (11)

$$(13) \quad F \oplus F' \vdash r_0^{+'} \models ex$$

By the induction hypothesis on (1), inversion of final on (2), (5), and (12)

(14)
$$F \oplus F' \vdash r^+ \models C_i \top$$

By inversion of example satisfaction on (14)

(15)
$$r^+ = C_i r^{+'}$$

By inversion of resumption on (4), noting that on account of (15), (12) is the first premise of R-Case and precludes R-Case-Indet

(16)
$$F \oplus F' \vdash ([E] \operatorname{fix} x_i (\lambda x_i.e_i)) r^{+'} \Rightarrow r'$$

By inversion of resumption on (16)

(17)
$$F \oplus F' \vdash [E] \text{ fix } x_j (\lambda x_j.e_j) \Rightarrow [E'] \text{ fix } x_j (\lambda x_j.e_j)$$

(18)
$$F \oplus F' \vdash r^{+'} \Rightarrow r^{+}$$

(18)
$$F \oplus F' \vdash r^{+'} \Rightarrow r^{+'}$$

(19) $(E', x_j \mapsto r^{+'}) \vdash e_j \Rightarrow r^*$

(20)
$$F \oplus F' \vdash r^* \Rightarrow r'$$

By Theorem A.11 (Res. Comp.) on (8) and (11)

$$(21) \quad F \oplus F' \vdash r_0 \Rightarrow r_0^{+'}$$

By R-UNWRAP-CTOR on (12), observing (15)

$$(22) \quad F \oplus F' \vdash C_i^{-1} \quad r \Longrightarrow r^{+'}$$

By Theorem A.12 (Eval. Respects Env. Res.) on (17/22), (7), (19), (21), and (20)

(23)
$$r' = r_0^+$$

Goal is given by (13), noting (23)

► Case 5: *U-Inverse-Ctor*.

- **▶** Given:
 - (1) $F \oplus F' \models K$
 - (2) C^{-1} r final
 - (3) $F \vdash C^{-1} r \Leftarrow ex \dashv K$
 - (4) $F \oplus F' \vdash C^{-1} r \Rightarrow r'$
- ► Goal:

$$F \oplus F' \vdash r' \models ex$$

By inversion of unevaluation on (3)

(5)
$$F \vdash r \Leftarrow C \ ex \dashv K$$

By the resumption assumption

(6)
$$F \oplus F' \vdash r \Rightarrow r^+$$

By the induction hypothesis on (1), inversion of final on (2), (5), and (6)

(7)
$$F \oplus F' \vdash r^+ \models C \ ex$$

By inversion of example satisfaction on (7)

(8)
$$r^+ = C r^{+'}$$

(9)
$$F \oplus F' \vdash r^{+'} \models ex$$

By R-UNWRAP-CTOR on (6), observing (8)

(10)
$$F \oplus F' \vdash C^{-1} r \Rightarrow r^{+'}$$

By Theorem A.5 (Determinism of Resumption) on (4) and (10)

(11)
$$r' = r^{+'}$$

Goal is given by (9), observing (11)

► Case 6: U-CASE-GUESS.

▶ Given:

- (1) $F \oplus F' \models (-; F_q) \oplus K$
- (2) ([E] case r of $\{C_i \ x_i \rightarrow e_i\}^{i \in [n]}$) final
- (3) $F \vdash [E] \operatorname{case} r \operatorname{of} \{C_i \ x_i \to e_i\}^{i \in [n]} \Leftarrow ex \dashv (-; F_q) \oplus K$
- (4) $F \oplus F' \vdash [E] \operatorname{case} r \operatorname{of} \{C_i \ x_i \to e_i\}^{i \in [n]} \Rightarrow r'$

► Goal:

$$F \oplus F' \vdash r' \models ex$$

By inversion of unevaluation on (3)

- (5) $F_a = Guesses(\Delta, \Sigma, r)$
- (6) $F \oplus F_q \vdash r \Rightarrow C_i r_i$
- (7) $F \oplus F_a \vdash e_i \rightleftharpoons ((E, x_i \mapsto r_i) \vdash \bullet \models ex) \dashv K$

By inversion of the check judgment on (7)

- (8) $(E, x_i \mapsto r_i) \vdash e_i \Rightarrow r_0$
- (9) $F \oplus F_q \vdash r_0 \Rightarrow r'_0$
- (10) $F \oplus F_q \vdash r_0' \Leftarrow ex \dashv K$

By (1) and the definition of \oplus , F_g and the second component of K must be consistent. Likewise, by (6) and others, F and F_g are consistent. By the definition of constraint satisfaction, $F \oplus F'$ must be a supermapping of the second component of $(-; F_g) \oplus K$, which, noting the previous observations, means F' is a supermapping of F_g

- (11) $F \oplus F' = F \oplus F_q \oplus (F' \setminus F_q)$
- (12) $F \oplus F' \models K$

By the resumption assumption

(13)
$$F \oplus F' \vdash r'_0 \Rightarrow r_0^+$$

By the induction hypothesis on (12) (observing (11)), Theorem A.6, (10), and (13)

(14)
$$F \oplus F' \vdash r_0^+ \models ex$$

By Resumption Composition on (9) and (13) (observing (11))

(15)
$$F \oplus F' \vdash r_0 \Rightarrow r_0^+$$

By the resumption assumption

(16)
$$F \oplus F' \vdash r_j \Rightarrow r_i^+$$

By R-CTOR on (16)

$$(17) \quad F \oplus F' \vdash C_j \quad r_j \Rightarrow C_j \quad r_j^+$$

By Theorem A.11 (Res. Comp.) on (6) and (17) (observing (11))

(18)
$$F \oplus F' \vdash r \Rightarrow C_j r_i^+$$

By inversion of resumption on (4), noting that (18) is the first premise of R-Case and precludes R-Case-Indet

(19)
$$F \oplus F' \vdash ([E] \operatorname{fix} x_i (\lambda x_i.e_i)) r_i^+ \Rightarrow r'$$

By the resumption assumption

(20)
$$F \oplus F' \vdash E \Rightarrow E^+$$

By R-Fix on (20)

(22)
$$F \oplus F' \vdash [E] \text{ fix } x_j (\lambda x_j.e_j) \Rightarrow [E^+] \text{ fix } x_j (\lambda x_j.e_j)$$

By inversion of resumption on (19), noting that (22) is the first premise of R-APP and precludes R-APP-INDET

(23)
$$F \oplus F' \vdash r_j^+ \Rightarrow r_j^+$$
 (noting Theorem A.8 (Res. Idemp.) on (16))

(24)
$$(E^+, x_j \mapsto r_i^+) \vdash e_j \Rightarrow r^*$$

(25)
$$F \oplus F' \vdash r^* \Rightarrow r'$$

By the definition of environment resumption, (20), and (16)

(26)
$$F \oplus F' \vdash (E, x_j \mapsto r_j) \Rightarrow (E^+, x_j \mapsto r_j^+)$$

By Theorem A.12 (Eval. Respects Env. Res.) on (26), (8), (24), (15), and (25)

(27)
$$r' = r_0^+$$

Goal is given by (14), observing (27)

THEOREM A.22 (CHECK)

Proof.

▶ Given:

(1) $F \oplus F' \models K$

(2)
$$F \vdash e \rightleftharpoons \{(E_i \vdash \bullet \models ex_i)\}^{i \in [n]} \dashv K$$

► Goal:

$$F \oplus F' \vdash e \models \{(E_i \vdash \bullet \models ex_i)\}^{i \in [n]}$$

By inversion of checking on (2)

(3)
$$E_i \vdash e \Rightarrow r_i$$

(4)
$$F \vdash r_i \Rightarrow r'_i$$

Proc. ACM Program. Lang., Vol. 4, No. ICFP, Article 109. Publication date: August 2020.

(5)
$$F \vdash r'_i \Leftarrow ex_i \dashv K_i$$

(6)
$$K = K_1 \oplus \ldots \oplus K_n$$

By Theorem A.6 on (4)

(7) r'_i final

By the resumption assumption

(8)
$$F \oplus F' \vdash r'_i \Rightarrow r''_i$$

By Theorem A.21 (Ex. Uneval.) on (1) (observing (6)), (7), (5), and (8)

(9)
$$F \oplus F' \vdash r_i'' \models ex_i$$

By Theorem A.11 (Resumption Composition) on (4) and (8)

(10)
$$F \oplus F' \vdash r_i \Rightarrow r_i''$$

Goal is given by SAT on (3), (10), and (9)

THEOREM A.23 (REFINE)

Proof. We consider only the most complicated case, Refine-Fix, in detail. The other cases are straightforward by similar reasoning.

▶ Given:

(1)
$$\Sigma$$
; Δ ; $(\Gamma \vdash \bullet : T \models X) \rightsquigarrow_{\text{refine}} e \dashv \{ (\Gamma_i \vdash \bullet_{h'_i} : T'_i \models X_i) \}^{i \in [n]}$

(2)
$$\{F \vdash ??_{h'_i} \models X_i\}^{i \in [n]}$$

► Goal:

$$F \vdash e \models X$$

By inversion of Refine on (1), assuming we go through Refine-Fix

(3)
$$Filter(X) = \{(E_i \vdash \bullet \models \{v_i \rightarrow ex_i\})\}^{j \in [m]}$$

- (4) h_1 fresh
- (5) $e = \text{fix } f(\lambda x. ??_{h_1})$

(6)
$$(\Gamma_1 \vdash \bullet_{h'_1} : T'_1 \models X_1) = ((\Gamma, f \mapsto (T_1 \rightarrow T_2), x \mapsto T_1) \vdash \bullet_{h_1} : T_2 \models X_1)$$

$$(7) \quad X_1 = \{ ((E_j, f \mapsto [E_j] \text{ fix } f (\lambda x. ??_{h_1}), x \mapsto v_j) \vdash \bullet \models ex_j) \}^{j \in [m]}$$

By inversion of Sat on (2), observing (6) and (7)

(8)
$$(E_j, f \mapsto [E_j] \text{ fix } f(\lambda x.??_{h_1}), x \mapsto v_j) \vdash ??_{h_1} \Rightarrow r_j^*$$

(9)
$$F \vdash r_i^* \Rightarrow r_i^{*'}$$

$$(10) \quad F \vdash r_j^{*'} \models ex_j$$

Proc. ACM Program. Lang., Vol. 4, No. ICFP, Article 109. Publication date: August 2020.

By E-Fix, observing (5)

(11)
$$E_j \vdash e \Rightarrow [E_j] \operatorname{fix} f(\lambda x. ??_{h_1})$$

By the resumption assumption

(12)
$$F \vdash E_j \Rightarrow E'_i$$

By R-Fix on (12)

(13)
$$F \vdash [E_j] \text{ fix } f(\lambda x.??_{h_1}) \Rightarrow [E'_j] \text{ fix } f(\lambda x.??_{h_1})$$

By Theorem A.9 (Simple Value Resumption)

(14)
$$F \vdash v_i \Rightarrow v_i$$

By Theorem A.8 (Idempotency of Resumption) on (13)

(15)
$$F \vdash [E'_j] \text{ fix } f(\lambda x.??_{h_1}) \Rightarrow [E'_j] \text{ fix } f(\lambda x.??_{h_1})$$

By the evaluation assumption

$$(16) \quad (E_i', f \mapsto [E_i'] \text{ fix } f (\lambda x.??_{h_1}), x \mapsto v_j) \vdash ??_{h_1} \Rightarrow r_i^{**}$$

By the resumption assumption

$$(17) \quad F \vdash r_i^{**} \Rightarrow r_i^{**'}$$

By the definition of environment resumption, (12), (13), and (14)

$$(18) \quad F \vdash (E_i, f \mapsto [E_i] \text{ fix } f (\lambda x.??_{h_1}), x \mapsto v_i) \Rightarrow (E_i', f \mapsto [E_i'] \text{ fix } f (\lambda x.??_{h_1}), x \mapsto v_i)$$

By Theorem A.12 (Eval. Respects Env. Res.) on (18), (8), (16), (9), and (17)

(19)
$$r_i^{**'} = r_i^{*'}$$

By R-App on (15), (14), (trivial), (16), and (17), observing (19)

(20)
$$F \vdash ([E'_i] \text{ fix } f(\lambda x.??_{h_1})) \ v_j \Rightarrow r_i^{*'}$$

By XS-INPUT-OUTPUT on (20) and (10)

(21)
$$F \vdash [E'_j] \text{ fix } f(\lambda x. ??_{h_1}) \models \{v_j \rightarrow ex_j\}$$

Goal is given by SAT on (11), (13), and (21), observing (3) and the fact that the filtered-out example constraints are trivially satisfied.

THEOREM A.24 (BRANCH)

Proof.

▶ Given:

$$(1) \quad \Sigma; \Delta; F; \underbrace{(\Gamma \vdash \bullet : T \models X)}_{\text{branch}} \leadsto_{\text{branch}} e' \dashv \{\underbrace{(\Gamma_i \vdash \bullet_{h_i} : T_i' \models X_i)}_{i}\}^{i \in [n]}; K$$

(2)
$$F \oplus F' \models K$$

(3)
$$\{ F \oplus F' \vdash ??_{h_i} \models X_i \}^{i \in [n]}$$

► Goal:

$$F \oplus F' \vdash e' \models X$$

By inversion of branch on (1)

- (4) $\Sigma(D) = \{C_i \ T_i\}^{i \in [n]}$
- (5) $(\Gamma \vdash \bullet : D) \rightsquigarrow_{\text{guess}} e$
- (6) $E_i \vdash e \Rightarrow r_i$
- (7) $F \vdash e \rightleftharpoons (E_j \vdash \bullet \models C_{\alpha_i} \top) \dashv K_j$
- (8) h_i fresh
- $(9) \quad (\Gamma_i \vdash \bullet_{h_i} : T_i' \models X_i) = ((\Gamma, x_i \mapsto T_i) \vdash \bullet_{h_i} : T \models X_i)$
- (10) $X_i = \{((E_j, x_i \mapsto [\![C_i^{-1} r_j]\!]) \vdash \bullet \models ex_j)\}^{j \in [m] \land C_{\alpha_j} = C_i}$
- (11) $Filter(X) = \{(E_j \vdash \bullet \models ex_j)\}^{j \in [m]}$
- (12) $e' = \text{case } e \text{ of } \{C_i \ x_i \to ??_{h_i}\}^{i \in [n]}$
- (13) $K = K_1 \oplus \ldots \oplus K_m$

Now, for each j, there are two cases, depending on whether or not e evaluates to a constructor form $(C_i \ r_i^* \text{ for } i = \alpha_i).$

► Case A: e evaluates to C_i r_i^* for $i = \alpha_j$.

(A1)
$$\alpha_i = i$$

(A2)
$$r_i = C_i r_i^*$$

(A1) $\alpha_j = i$ (A2) $r_j = C_i \ r_j^*$ By inversion of Sat on (3), observing (10), (A2), and E-Hole

(A3)
$$(E_j, x_i \mapsto r_j^*) \vdash ??_{h_i} \Rightarrow [E_j, x_i \mapsto r_j^*] ??_{h_i}$$

(A4)
$$F \oplus F' \vdash [E_j, x_i \mapsto r_j^*] ??_{h_i} \Rightarrow r_j^{*+}$$

(A5) $F \oplus F' \vdash r_j^{*+} \models ex_j$

(A5)
$$F \oplus F' \vdash r_i^{*+} \models ex_i$$

By E-Case on (6) (observing (A2)) and (A3), observing (12) (A6) $E_j \vdash e' \Rightarrow [E_j, x_i \mapsto r_j^*]$?? h_i

(A6)
$$E_j \vdash e' \Rightarrow [E_j, x_i \mapsto r_i^*]??_h$$

Goal is given by SAT on (A6), (A4), and (A5), observing (11) and the fact that the filtered-out example constraints are trivially satisfied.

► Case B: e does not evaluate to a constructor form.

(B1)
$$r_j \neq C_i r_i^*$$

(B1) $r_j \neq C_i \ r_j^*$ By the resumption assumption

(B2)
$$F \oplus F' \vdash E_j \Rightarrow E'_i$$

By Theorem A.22 (Ex. Check.) on (2) (observing (13)), and (7) $\,$

(B3)
$$F \oplus F' \vdash e \models (E_j \vdash \bullet \models C_{\alpha_j} \top)$$

By inversion of Sat on (B3), observing (6)

(B4)
$$F \oplus F' \vdash r_j \Rightarrow r_i^+$$

(B5)
$$F \oplus F' \vdash r_j^+ \models C_{\alpha_j} \top$$

By inversion of example satisfaction on (B5)

(B6)
$$r_i^+ = C_{\alpha_i} r_i^{+*}$$

By R-UNWRAP-CTOR on (B4), observing (B6)

(B7)
$$F \oplus F' \vdash C_{\alpha_j}^{-1} r_j \Rightarrow r_j^{+*}$$

By Theorem A.8 (Idempotency of Resumption) on (B4), observing (B6)

(B8)
$$F \oplus F' \vdash C_{\alpha_i} r_i^{+*} \Rightarrow C_{\alpha_i} r_i^{+*}$$

By inversion of resumption on (B8)

(B9)
$$F \oplus F' \vdash r_i^{+*} \Rightarrow r_i^{+*}$$

Below, unless otherwise noted, $i = \alpha_j$

By the definition of environment resumption, (B2), and (B9)

(B10)
$$F \oplus F' \vdash (E_j, x_i \mapsto r_i^{+*}) \Rightarrow (E'_i, x_i \mapsto r_i^{+*})$$

By E-Hole

(B11)
$$(E'_j, x_i \mapsto r_j^{+*}) \vdash ??_{h_i} \Rightarrow [E'_j, x_i \mapsto r_j^{+*}] ??_{h_i}$$

By the resumption assumption

(B12)
$$F \oplus F' \vdash [E'_i, x_i \mapsto r_i^{+*}] ??_{h_i} \Rightarrow r_i^{++'}$$

By inversion of Sat on (3), observing (10), (B1), and E-Hole

(B13)
$$(E_j, x_i \mapsto C_i^{-1} r_j) \vdash ??_{h_i} \Rightarrow [E_j, x_i \mapsto C_i^{-1} r_j] ??_{h_i}$$

(B14)
$$F \oplus F' \vdash [E_j, x_i \mapsto C_i^{-1} r_j] ??_{h_i} \Rightarrow r_j^{*+}$$

(B15)
$$F \oplus F' \vdash r_j^{*+} \models ex_j$$

By the definition of environment resumption, (B2), and (B7)

(B16)
$$F \oplus F' \vdash (E_j, x_i \mapsto C_i^{-1} r_j) \Rightarrow (E'_j, x_i \mapsto r_j^{+*})$$

By Theorem A.12 (Eval. Respects Env. Res.) on (B16), (B13), (B11), (B14), and (B12)

(B17)
$$r_i^{*+} = r_i^{++'}$$

By E-Case-Indet on (6), and (B1), observing (12)

(B18)
$$E_i \vdash e' \Rightarrow [E_i] \operatorname{case} r_i \text{ of } \{C_i \mid x_i \rightarrow ??_{h_i}\}^{i \in [n]}$$

By R-Fix on (B2)

(B19)
$$F \oplus F' \vdash [E_j] \text{ fix } x_i (\lambda x_i.??_{h_i}) \Rightarrow [E'_i] \text{ fix } x_i (\lambda x_i.??_{h_i})$$

By R-App on (B19), (B9), (trivial), (B11), and (B12)

(B20)
$$F \oplus F' \vdash ([E_j] \operatorname{fix} x_i (\lambda x_i.??_{h_i})) r_i^{+*} \Rightarrow r_i^{++'}$$

By R-Case on (B4) (observing (B6)) and (B20)

(B21)
$$F \oplus F' \vdash [E_j]$$
 case r_j of $\{C_i \mid x_i \rightarrow ??_{h_i}\}$ $i \in [n] \Rightarrow r_i^{++'}$

Goal is given by SAT on (B18), (B21), and (B15) (observing (B17)), observing (11) and the fact that the filtered-out example constraints are trivially satisfied.

THEOREM A.25 (FILL)

Proof. The Defer case is trivial. The Refine, Branch case is straightforward by way of Theorem A.23 (Refine) and Theorem A.24 (Branch). The Guess-And-Check case is straightforward by way of Theorem A.22 (Check). □

THEOREM A.26 (Type soundness of merge)

Proof. Straightforward by way of induction and (eventually) Theorem A.14. Technically, we must establish similar lemmas applying to Step and Resolve, but the definitions and proofs of these lemmas are straightforward.

THEOREM A.27 (EXAMPLE SOUNDNESS OF MERGE)

Proof. Straightforward by way of induction and (eventually) Theorem A.22 (Check). Technically, we must establish similar lemmas applying to STEP and RESOLVE, but the definitions and proofs of these lemmas are straightforward.

THEOREM A.28 (SOUNDNESS OF SOLVE)

Proof.

► Given:

- (1) $\Sigma \vdash U : \Delta$
- (2) $\Sigma \vdash F : \Delta$
- (3) Σ ; Δ ; $Solve(U, F) \rightsquigarrow F'$; Δ''

► Goal A:

$$\Sigma \vdash F' : \Delta''$$

► Goal B:

Proc. ACM Program. Lang., Vol. 4, No. ICFP, Article 109. Publication date: August 2020.

$$F' \models (U; F)$$

By inversion of Solve on (3), going through Solve-One rule since Solve-Done is trivial

- (4) $h \in dom(U)$
- (5) $\Delta(h) = (\Gamma \vdash \bullet : T)$
- (6) U(h) = X
- (7) F; $(\Gamma \vdash \bullet_h : T \models X) \leadsto_{\text{fill}} K$; Δ'
- (8) Σ ; $\Delta + \Delta'$; $Merge((U \setminus h; F) \oplus K) \triangleright K'$
- (9) Σ ; $\Delta + \Delta'$; $Solve(K') \rightsquigarrow F'$; Δ''

By definition of constraints typing on (1), (5), and (6)

(10) Σ ; $\Delta \vdash X : \Gamma$; T

By Theorem A.17 (Type Soundness of Fill) on (2), (10), and (7)

(11)
$$\Sigma \vdash K : \Delta + \Delta' + (h \mapsto (\Gamma \vdash \bullet : T))$$

By (11), observing (4) and (5)

(12)
$$\Sigma \vdash K : \Delta + \Delta'$$

By observing that freshness premises ensure that Δ' is disjoint from Δ

- (13) $\Sigma \vdash U : \Delta + \Delta'$
- (14) $\Sigma \vdash F : \Delta + \!\!\!\! + \Delta'$

By Theorem A.26 (Type Soundness of Sem. Merge) on (12+13+14) and (8)

(15)
$$\Sigma \vdash K' : \Delta +\!\!\!+ \Delta'$$

By the induction hypothesis on (15), (15), and (9)

- (16) $\Sigma \vdash F' : \Delta''$
- (17) $F' \models K'$

By Theorem A.27 (Ex. Soundness of Sem. Merge) on (17) and (8)

(18)
$$F' \models (U \setminus h; F) \oplus K$$

By the definition of constraint satisfaction and (18)

- (19) $F' \models (U \setminus h; F)$
- (20) $F' \models K$

By Theorem A.25 (Ex. Soundness of Fill) on (7) and (20) (observing (19))

- (21) F'(h) = e
- (22) $F' \vdash e \models X$

By straightforward reasoning on (21) and (22)

(23)
$$F' \vdash ??_h \models X$$

Goal A is given by (16)

Goal B is given by combining (19), (6), and (23)

THEOREM A.29 (SOUNDNESS OF ASSERTION SIMPLIFICATION)

Proof. Straightforward by way of Theorem A.32.

THEOREM A.30 (SOUNDNESS OF SYNTHESIS)

Proof. Straightforward by way of Theorem A.20, Theorem A.19, Theorem A.28 (solve) and Theorem A.29.

THEOREM A.31

Proof. Straightforward induction.

THEOREM A.32

Proof.

► Given:

- (1) v simple value
- (2) r final
- (3) $\vdash r \Leftarrow v \dashv K$
- (4) $F \models K$

▶ Goal:

$$F \vdash r \Rightarrow v$$

By the resumption assumption

(5)
$$F \vdash r \Rightarrow r'$$

By Theorem A.21 (Soundness of Example Unevaluation) on (4), (2), (3), and (5)

(6)
$$F \vdash r' \models v$$

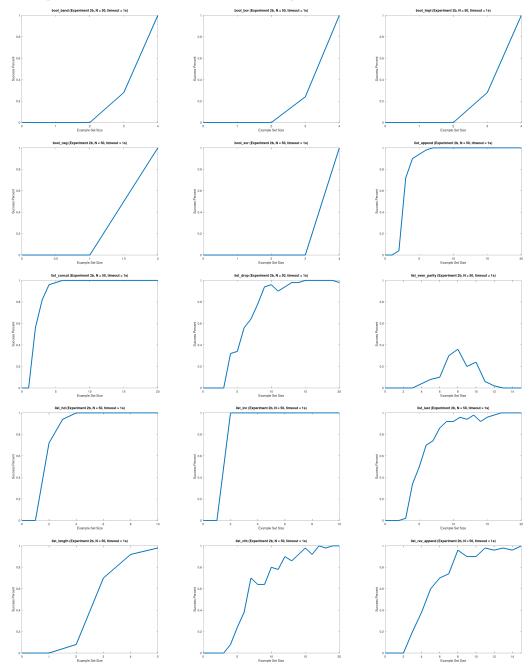

By Theorem A.31 (Example Satisfaction of Simple Value) on (1) and (6)

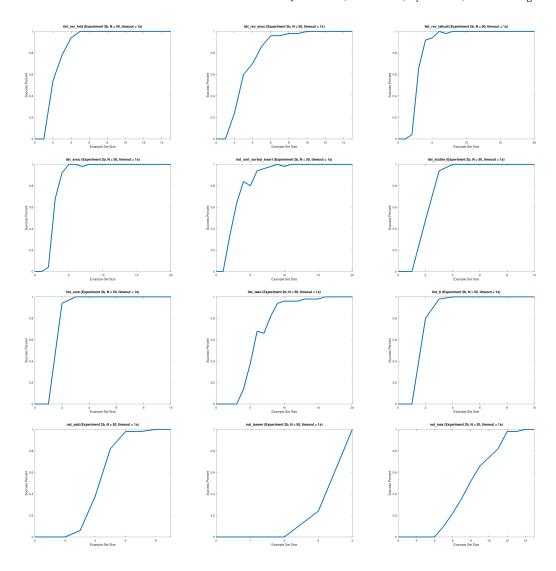

(7)
$$r' = v$$

Goal is given by (5), observing (7)

B ADDITIONAL EXPERIMENTAL RESULTS

B.1 Experiment 2b: No Sketch + Random Examples

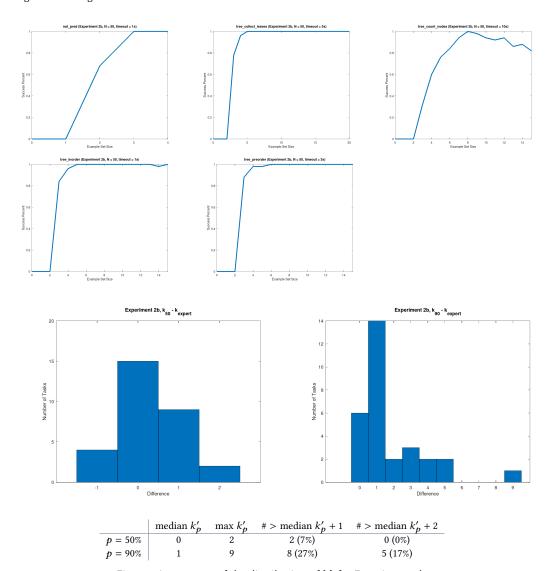

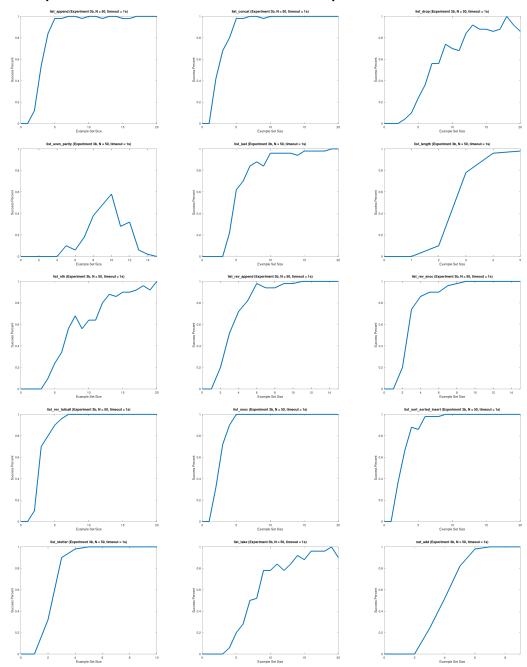

Fig. 18. A summary of the distribution of k_p^\prime for Experiment 2b.

B.2 Experiment 3b: Base Case Sketch + Random Examples

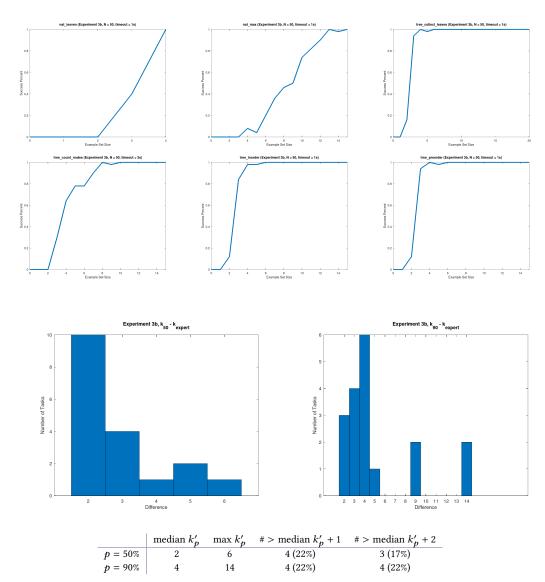

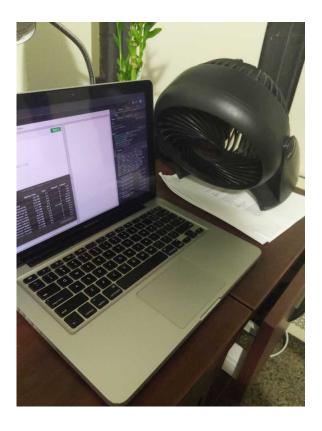

Fig. 19. A summary of the distribution of k_p^\prime for Experiment 3b. (Does not include list_concat due to failure in Experiment 3a.)

B.3 Experimental Setup (circa February 2020)

C POLYMORPHISM

C.1 Implementation

The SMYTH implementation supports System F universal polymorphism, as well as user-defined polymorphic type operators such as the following:

```
type List a = Nil | Cons a (List a)
```

The MYTH thesis [Osera 2015, Ch. 9] details how to extend MYTH to include System F universal polymorphism (and the details generalize as expected in SMYTH), but does not include a description of how to support polymorphic type operators.

Polymorphic Type Operators. The changes to the SMYTH codebase to support polymorphic type operators were largely straightforward except for in one place: synthesis of case scrutinees. When synthesizing a case scrutinee, MYTH and SMYTH attempt synthesis at every datatype in scope. But with the inclusion of a single polymorphic type operator (and a base type), there are an infinite number of datatypes in scope—for example, List Nat, List (List Nat), List (List Nat)), etc. All of these are valid types for the scrutinee of a case expression. Raw term enumeration occurs at a single type, but in this instance there is an infinite family of types that serve as the goal to term enumeration.

To capture this notion of an infinite class of types, we introduced the simple notion of a *type* wildcard (*) to SMYTH and straightforwardly extended the standard syntactic notion of type equality (=) to *type matching* (\equiv_*):

$$\frac{\tau \text{ Type} \quad \sigma \text{ Type}}{\tau \equiv_* \sigma} \qquad \frac{\tau = \sigma}{\tau \equiv_* \tau} \qquad \frac{\tau \text{ Type}}{\tau \equiv_* \tau} \qquad \frac{\tau \text{ Type}}{\tau \equiv_* \tau}$$

Scrutinee synthesis then occurs as before (once per datatype), but with polymorphic datatypes instantiated with the wildcard type. Raw term enumeration then substitutes equality for type matching wherever necessary to compensate.

Examples for Polymorphic Types. For the purpose of specifying examples for polymorphic functions, the MYTH thesis [Osera 2015, Ch. 9] introduces "polymorphic constants" (called "abstract refinements" by Frankle et al. [2016]). Later in the chapter, "boxed" concrete examples are presented as an equally-expressive alternative to polymorphic constants.

Neither of these apparatuses is necessary in SMYTH; examples can be specified by normal function application and type argument application, and live unevaluation will transform the examples to hole constraints, albeit with a polymorphic type so that concrete refinements of these examples cannot be performed. (This is the crux of why fewer examples are needed to correctly synthesize polymorphic functions in SMYTH.) For example, consider the following synthesis task:

```
stutter : forall a . List a -> List a
stutter <a> xs = ??

spec (stutter <Nat>)
  [ ([], [])
  , ([1, 0], [1, 1, 0, 0])
  ]
```

SMYTH correctly synthesis a polymorphic version of the stutter function when given this sketch. Notice that spec is called with the argument stutter <Nat> (a type argument aplication), so

the examples can be provided monomorphically (the implementation requires a few additional annotations to simplify typechecking). The assertions could alternatively be specified as follows:

```
spec2 stutter
  [ (<Nat>, [], [])
  , (<Nat>, [1, 0], [1, 1, 0, 0])
  ]
```

demonstrating that no special machinery is needed to handle examples for polymorphic functions other than the live unevaluation rules for type argument application.

C.2 Experiments 5 and 6

Of the 38 tasks that succeeded in Experiment 1, 23 can be specified with a polymorphic type signature rather than a monomorphic one. Figure 20 summarizes the results of re-running Experiments 2 and 3 on these 23 tasks given polymorphic type signatures; Experiment 5 is the polymorphic version of Experiment 2, and Experiment 6 is the polymorphic version of Experiment 3. The process for correctness checking, expert example selection, and random example generation are the same as in earlier experiments.

In summary, polymorphic examples offer a modest reduction in the number of examples needed for synthesis. More qualitatively, they ensure that example providers need not worry about specifically crafting examples that do not "overlap" in the sense that they happen to share incidental refinements that do not generalize to the correct solution.
